The tubes were obviously no longer needed, since they were replaced by smaller and more efficient solid state devices. They could have been rejects too. I noticed some variations in their characteristics that may not have been intentional. As for designed obsolescence, I don't think they were intended to fail after X number of hours. Rather they were intended to last at least X number of hours, as a glass half empty or half full. Ordnance equipment was usually held to a higher standard the other equipment.

If you mean the Space Rambler schematic, this might help you:

http://radioremembered.org/images/WesternRadio/WRBR1.Schematic.JPG

Your reproduction could use something like miniature 7-pin tube plugs for the plug-in coil base.

The original used tiny cardboard coilforms around the diameter of a pencil, rather fragile for any extended use.
Note that there’s no bandspread, which is a serious drawback on the high band at least.

I would change that front panel antenna control, put the trimmer there in parallel with the tuning capacitor,

and either move the antenna trimmer to the rear panel or even outboard. Bandspread control is much more

used in moment-to-moment tuning around.

Hi Mike,

I wish I had the schematic.

That's very cool! Interestingly, the ad claims it's a super-regen. "Order now before the price goes up."

I have a BN-1 and never knew until very recently that Weskit made anything else. The BN-1 seemed so obscure to me that I figured it was a one-off.

From: Hubert Miller
Topic: 26731 Message: 26731

Re the Space Rambler schematic - i don't know about you, but i really didn't like the way the coil plug-in is drawn.
It seems to me it's drawn for my maximum puzzlement.

At risk of boring some, here's what is going on:

Coils A 0.55-1.6 B 1.55-4.2 C 3.75-10.5 MHz

hot (top) end of tuning coil pin 1 - goes to grid of 1L4 and tuning capacitor section C3-1

coil pin 1 is jumpered inside to pin 3 - goes to second section of tuning capacitor C3-2, so that on these bands A B C

the two sections of tuning cap are paralleled

Coil pin 7 goes to ground.

Coil pin 2 feedback winding goes to 1L4 plate

Coil pin 6 feedback winding goes to B+

Coil D 10-22 MHz

does not have jumper connecting pins 1 and 3 inside; otherwise same as above.

So 2nd section of tuning cap C3-2 is not connected, not used. The coil is tuned only by tuning cap section C3-1 to limit the MHz

coverage of this coil.

Coil E 18-42 MHz

hot (grid) end of coil pin 1 goes to 1L4 grid (and tuning cap section C3-1)

other end of tuning coil pin 3 connects to tuning cap section C3-2

coil has a built-in 47 pF cap which connects its pin 3 and pin 2

this capacitor at coil pin 2 connects to 1L4 plate

So the tuned circuit is between plate and grid, with the ground of tuning cap sections C3-1 and C3-2 at ground, "center tap".
For this 18-42 MHz band, the oscillator does not use a feedback winding - it is a Colpitts oscillator

1L4 gets its B+ from a small choke built into the plug-in coil at pin 2. The other end of the choke is coil pin 6 which goes to

B+.

Coil E does not use its pin 7

18-42 MHz on Band E is quite a large swath for not having any bandspread control, which is why i think a front-panel bandspread

would be more useful than an antenna trimmer. Can you imagine trying to tune in 27 MHz CB or 28 MHz ham band with no

bandspead control?

says Hue

From: Jim Scott
Topic: 26646 Message: 26734

Weren't the TRF sets more expensive? Even though the circuits were simple, the components were expensive. I would think the addition of additional tuning circuits and additional tube would have added a lot of cost.

If you want to build a TRF receiver, there is a source for the dual gang 365mmf variable at the xtalset society buy/sell page for about $20 US.

www.midnightscience.com

Hope that helps.

Mendelsons in Dayton Ohio had boxes of 100 in their tube room for $2.50 each tube. You got an extreme bargain. Do your tubes have the pinch at the end of the tube where the wires exit in the shape of an "X"? There were no markings on the tubes except a single number like 45, 33, 48 etc.

There's no pinch on the lead end of the tube. The 5 leads come out in a circle. There was supposed to be a red dot or mark for the plate lead but these don't have it. I check for the filament leads first. The grid lead is between them. The other 2 leads are the screen and plate.

I tried the diode in a crystal set but it didn't work as well as a 1N34. The thyratrons will probably not see any use.

I was looking at an ad in Electronics Illustrated, Dec. 1960, p 22, for the “Ekeradio FM tuner”;

they say sold from 1947 to the date. The photo shows it with one submini tube. The tube has

a flattened package rather than round, and the whole tube is a solidl grey color. I’m sure it was

a 1.5 volt tube. I’m not real familiar with subminis, so i’m wondering what tube that might be.

As it’s a superregen detector, i think it was a triode. Ideas? I actually have parts of the unbuilt

kit, no tube or instructions.

I was looking at an ad in Electronics Illustrated, Dec. 1960, p 22, for the “Ekeradio FM tuner”;

they say sold from 1947 to the date. The photo shows it with one submini tube. The tube has

a flattened package rather than round, and the whole tube is a solidl grey color. I’m sure it was

a 1.5 volt tube. I’m not real familiar with subminis, so i’m wondering what tube that might be.

As it’s a superregen detector, i think it was a triode. Ideas? I actually have parts of the unbuilt

kit, no tube or instructions.

Incidentally, my 433 and 447 tubes are round triodes and are slightly larger than my other subminis, They have the pinch at the bottom with the leads in a straight row. The proximity tubes are slightly bigger than an NE-2 and have a "button" base.

Leonard

That's an interesting guess and it would make sense. The question is that whether the 50% feedback ratio is enough to force it into squegging, =superregeneration.
But i don't recall anything about that in the instructions. Seems like i would have remembered if different procedure was called out for band 18-42 MHz. Maybe not. I don't know where i have the instructions right now.

Subject: Re: [regenrx] Weskit BR-1
Thanks, Mike. My *guess* is that it's a regen on the lower bands and a super-regen (aka "rush" box) on the highest band. Very clever.

Readers today of such articles as the 1934 Short Wave Craft “Oscillodyne” circuit wonder how such an ordinary Armstrong

regenerative circuit could possibly be called “superregen”. Is it a mistake or maybe hype? When you look at the coil table

for the Oscillodyne (for example), you discover that the feedback winding is much larger than what you usually see. In fact,

for the high frequency band, the tickler winding may have the same, or even more turns than the main, tuned circuit winding.
If you provide massive feedback to the grid, you get periodic blocking action, squegging, and if you control the feedback

level, you can somewhat control the squegging rate. That’s one way to do a self-quenched superregen – probably the

way the phenomenon was discovered. In the BR-1, the 50% feedback tap via the voltage divider of series C3-1 and C3-2

is not enough probably for any kind of superregeneration. So the “superregeneration” term in the advert probably

should have read, “A Super Regenerator!” instead of “Superregenerative!”

I have told this story before, but maybe appropriate here: i had a Knight “Space Spanner” back in the mid-1980s. This

has a pretty basic ½ 12AT7 triode Armstrong regenerative. When i was listening on the 6 or 9 MHz band, i discovered

that by increasing the regen way past oscillation point, the thing went into superregenerative mode. For anyone

familiar with superregen sound, it was immediately apparent. Suddenly there was a loud rushing sound between signals;

volume on the same SW broadcast came way up from where it had been at the “optimum (critical) regeneration”

point, and the selectivity, ability to separate two AM HF stations, was 10x as wide. I didn’t investigate why it was able

go into this superregen mode; it wasn’t modified, so i would have to guess either the grid leak resistor increased in value

greatly, setting up a blocking oscillation, or there was something funky about the tube’s characteristics. Even disregarding

the selectivity degradation, it wasn’t an attractive deal: the reception was noisy, and the audio unpleasant. This was the

same judgement i made about the Radio Shack “AM-Shortwave Radio Kit”, the one with the cardboard backboard and

spring clips for connecting wires. It works, but you wouldn’t want to use it for actual listening.

Here’s a couple other advertising come-ons that Western Radio considered:

“Order now before the FTC investigates our claims!”

“Order now before we go out of business!”

>Subject: Re: [regenrx] Weskit BR-1

It's what appears to be a split-stator tuning cap that fooled me. I always associate them with super-regens. I thought the marketing hype was "order now before price goes up." Weskit trying to manipulate young minds.

Still, an intriguing little set.

I just built my take on it as some of you already know. i changed a couple of things and used a later tube but I owe the sets design to the original Weskit idea. I made it single tracking with a dual gang tuning cap, one side for the TX and one for the RX. I padded the TX side and aded a low value tuning cap on the RX side for sweeping to find the replying signal . I made the tx a VFO as well. I switched to hartley based circuits because i prefer them . I made both tx and rx coils identical and on slug tuned ceramic coil forms. I link coupled the antenna to each coil and switch it from TX to Rx as well as B+. i did not switch the heaters as the old Weskit did. After a successsfull fore up i added a Audio amp which was an option back in the day on some BN-1 sets. I could have got by without it s I could hear well enough but I had 12aq5 and a socket and a half dozen parts so i did it. The RX is absolutely phenomenal. I can hardly believe so few parts can work so well. Probably the most signal sensitive rx I own bare none. I have been playing with it everyday since for a few hours. My main dual triode I settled on fnally ws an ECC832 which is essentally 1/2 12ax7 (for the regen) and 1/2 12au7 (for the transmitter) I was ble to run the set on AC based power with no decernble hum when I finally finised it. here is the business end when it was first finished. I call it the DN-1. Fun to use and performs well. I would have said more earlier but just got home from NL so I missed the start. However I built mine this month so it is still fresh.

I built it for 40M and it will do 60M but I am rarely there so probably doesn't matter. It sound pretty decent to me. It is a little wobbly when cold but after about 15 minutes it is solid. It hs its own tone but it is not wild or anything. Input is around 6 watts (current measured across the key with cathode keying) Output is good but in all honesty it could probably use more however I have other rigs with less power that do fine on vintage nights so it should be OK. I havent had any contacts yet as everyone seems to busy to listen so i have been calling on and around 7040khz when I have time and it isnt occupied. I am tooo far from any skimmers to use a RBN as even my big rig has only run their bell twice that i know of. I have 45 watt rig standing by on the same freq which I fire up and try as well. Since neither is getting a reply the week before i went and last night I figure it isnt the rig so much as conditions and lack of activity. I also know that I and most other hams naturaly go back to the best signal we hear so a pipsqueak like this compared to a 100 watt Kenwood or Yaseau for instance has a tuff go. Unless of course someone is listening for it. So that is kind off frustrating because I did some field testing and SS testing nearby and i know it is a good as any of my vintage transmitters and better then some. Hopefully I will work someone soon. On the other hand the rx surpised me. Even with only the one triode section i could copy it seemed everything my DX394 can. Once i dded the 12aq5 audio amp and found its sweet spot (too much gain gives hum like any good amp but around 1/2 throttle there is none that I can hear) I can tune my Dx394 to a freq, give it its final tweak and max signal , tune the DN-1 to the same spot and hear the same. Then with about an extra 1.8th turn on the regen control (a 250k pot) step into signals the Dx394 can not hear. That surprises me and the parts count and complication of circuit design is quite low. I just love how the little thing works and even though I have only had a week and a bit of running it it is fun to use and I find myself turning it on everytime I am in my vintage shack. In fact I am on way downstairs now. It will run a speaker too although I prefer phones. I find myself grinning as I use it. Once i get a contact then I will be very happy. Range judging on past experience at similar power levels on the same antenna will be 60 to 200 miles so someone far side or Syracuse NY or London Ontario for instance would probably be good to go in current conditions and time of year. I am on the North Shore of Lake Ontario a bit east of centre.
Anyway I hope more of you built it or your take on it. I am enjoying mine. More then I expected to truth be known.

26758. Which way does this capacitor go..... INTERstage coupling

Yahoo group: regenrx (2016 — 2017)
Date: 2016-06-30 06:20:44 UTC
From: Rob
Topic: 26666 Message: 26758

I am not getting any audio out of the complete TDA7052 amp circuit using
a 10uF electrolytic cap.
It humps the speaker with a solid click.... then periodically humps the
speaker again.
I did not take note that it was a cyclic event until I replaced the 10uF
cap with a 1uF electrolytic
and then I got non-stop pop pop pop pop pop pop pop.

I built the amp circuit twice.... first with wire wrap..... then on
modern breadboard.
Getting the exact same results. pop pop pop pop pop pop

I listened to the original radio circuit when attached to a small
portable guitar amplifier.
I do not know the circuit in the guitar amp but it raises my curiosity
as to how interstage
connections are made between the guitar amp input and its amplifier and
what I might be needing to be an interstage connection between my 7.16
circuit
and my MPF102/TDA7052 circuit.
I have suspicions that my 7.16 circuit is passing so much DC into the
MPF102 circuit that
it just plows the speaker to solid humped "on".
Is a choke in order someplace here?

The pop, pop, pop might be motorboating, that is usually cause by an
insufficiently bypassed power supply, or not enough power.

Well while you lads have been postulating about the Weskit BN-1 etc I took a week off from working on my take on it and went to Holland for holiday. Now that i have returned I spent sometime optimizing best I could the transmitter output. Yesterday at 8 AM I did a QSO with Paul N1BUG on 7040khz. I received a 449 report and we pulled it of despite some QSB and heavy QRM near me. You might not be impressed but I was. S much so that my hand was shaking as I signed and I could hardly send Paul's call. That is 423 miles ATCF in less then optimum conditions . When you consider it is only 1/2 a tube so only single triode that comprises the whole transmitter I am impressed. The receiver continues to amaze me as well. Seems to work very well. As I mentioned I added a 12aQ audio amp but it did function to a usable level without it. The whole project turned out much better then i would have thought. That doesn't often happen. After working Paul I set it aside on the shelf till winter and real good conditions content in the knowledge I have a real good working transceiver for very few dollars and a lot of fun. If the original BN-1 works half as good then it is a heck of a radio.
BTW have already thought of modulating it. There are many ways to do it that work well and I have explored several over the years. Some dating as far back as pre 1920. Plate modulation isn't the only game in town. In fact it is rarely used commercialy.

What is the tuning range of your transceiver?
I think the 4 - 5 MHZ per turn of the original BN-1 tuning range would have made it very hard to use for DX.
What B+ did you use on the transmit section of the 3A5 valve?
tnx

FOR SALE: Morrow HF Mobile converter

Covers 80m, 40m, 20m, 15m and 10m

Lovely old nostalgia piece. It will convert these HF bands to appear on the AM (medium wave)
Band in your car radio - or other AM band receiver.

Pictures and details at:

http://af4k.com/radios.htm

Available for $50.00 plus shipping.

73 - Bry, AF4K

6.9 to 10.4mhz
I thought about padding it to tune 3.5 to 7.3 at least but it works so well I am not going to monkey with it.
Remember I did not build the BN-1 but my take on it.
So the main tuning tunes the ganged dual tuning cap which I robbed from an old receiver. Yes it is a bit fast especially on tranmit but still workable. It has a reduction but I wish it had more still it is very usable. If you want to work me on any freq it covers I will be there , right there. On Receive I added a bandspread cap so I can swing and find the signal. It has some gear reduction too but probably doesnt really need it. You need RIT so you can find the signal because as you know often even on modern rigs we re not always exactly on freq with the other station. This feature allows you to operate without touchng tx tune. I have this on my other transceiver, my first one and it came about after discovering I needed it so it is now part of how I build transceivers. So running the rx is not difficult at all and its performance surprises me. I built both circuits as I said before as hartleys (RX TX) . My TX is VFO not crystal. With crystal control it is a non issue.
I did not use the 3a5 as I didnt have one. I built it originally with a 12ax7 because I have several of them. They are a bit light on power being akin to a 12sl7 so I popped in a 12au7. The TX liked it but the regen behaved like a regen does with a 6sn7 (or 12sn7) Meaning it worked but not as lively. I said to my self it would be nice to have a tube that was half 12ax7 and half 12au7. I was poking around on some tube sites and came across the ECC832 which is exactly that. I found one from my favourite tube store and luckily its power side was where my set was wired for the TX and its voltage amp side was where my rx was wired so it was a plug in. (I am not usually that lucky) Instantly it picked up and worked as I had hoped. Actually far better then i had hoped. The Rx gives nothing away and I am thrilled with it. The TX was now drawing 6 watts and lighting my RF sniffer bulb so I knew it had enough power to communicate. Output wasnt as high as I wanted but enough. I played with the output link using a Christmas tree bulb to indicate actual RF out and revamped its position and number of turns to get good output. I installed a guset op in my chair and had them send some CW while I took a portable a few miles away to compare reception against my other homebrew single tube rigs . It was as good as the best and well above most . Voltage is 282v key down BTW.(A 3A5 doesn't need that much) Regen side runs on much less of course. So the set is putting out but no contacts. I have been there before. Often the weaker signals get ignored. I know because I do that myself. And it doesn't have that solid modern sound to it so newer hams get nervous. it has a slight chirp but slight not pronounced but still it sounds different. Summer activity is often spotty anyway so I tried to get a volunteer to listen for it. Seemed like it wasn't going to happen but Paul saw my post on a nearby sight asking and was there in minutes. He is an exceptional operator and has been in the same spot with some of his homebrew vintage rigs so understood immediately. I have never been in a vintage radio event that he hasn't worked me. He won the AWA BK event 2014 so you know he is good.
However he said he heard me from my initial CQ and gave me a 449. He is a long ways away for a small rig to hear in daytime. I had figured maybe some one in New York State (Syracuse area) would be about the limit for daytime ops so I am more then thrilled. He is more then double that from me. (423miles ATCF)

What I learned from the BN-1 which I took to designing this one was use each triode section independently. (one side for tx one side for RX) I hadn't thought of that simple a design before.
So using the concept they used I designed one that suited my junk box and experience. however if I had a BN-1 it would be on air in an instant. A single tube practical transceiver is a pretty pratical device. For clandestine WW11 radios it would have been perfect. I hate over-complication or should I say unnecessary complication of simple circuits so when something like this comes together and works so well I am very pleased to say the least. I intend to use it regularly.

I've built several regens, both solid and hollow state. They all worked, some better than others, but none of them have done as good a job as I'd like at demodulating SSB signals. I'd really like to remedy this.

A friend of mine recommended that I build a twinplex for this purpose. Are there any other circuits you'd suggest? I don't care whether it uses tubes or transistors so long as it's a strong performer on SSB.

The twinplex is a very good design. Probably one of the best. Keep the freq range low to your area of interest. I am moore then happy with mine and have used it and not been tempted to modify it for many years. (Probably 20 plus.)
I recently built a hartley based one which also works exceptionally well but I do not wish to muddy the waters as the twinplex with a 6sl7 or 12sl7 is more then up to the job. Just go for it.

Nothing says you couldn't use a choke in the lead of the second triode and then have a line out to a power amplifier. A small tube such as 6AQ5 or something would do. I have a 12A6 if you're looking for a more retro look (12A6 is an octal tube in a metal shell).

The twinplex will be just as bad on SSB as the rest of them unless you use very light tank coupling. Just enough to get good oscillation. If you want a solid SSB performer, check out a solid state regen I built a few months back.

I looked up the discussion of the two transistor regen on Radioboard. I just registered also; i hope i make the grade!

While looking there, i noticed a mention of a recent ‘crystal set field day’ in Beijing.

http://www.crystalradio.cn/thread-873197-1-1.html

Nice photos! Radio fun is international!

BTW, the article has me thinking of making some plug-in solidstate adapters for the National SW-3. It seems that

a high voltage power supply is always a stumbling block for me.

Also the mention of the FT-101 dial + tuning cap the regen builder used, reminded of a very dirty TS-511 transceiver

i bought – without the HV matching power supply. I had been wondering whether it deserves to be restored, or just

too much work for a project with not much to recommend it?

Now hold on a dang minute! The twinplex will copy SOLID SSB.all day long. I know because i have and use one regularly. I often sit here and read the mail in the SSB portion just for something to do while I am waiting for a sked . If you dont build a twinplex you will never know how well they work. Once you have one it is easy to understand why they were so popular. In fact many of the more exotic designs using beam power tubes etc are pure crap in comparison. (yes I have built and tried them)
I am also quite partial to hartley based regen including the one I just built for my transceiver. it copies SSB easily with out a fuss and willl run a speaker by the way although I prefer phones. However that said a well built regen of the twinplex design will give you a very practical and usable receiver that will give nothing away to your modern rxs. 6sl7 or 12sl7 are my favourites as they are very responsive compared to the N tubes. When using my single tube TX I always pair it with its matching twinplex. And I use a loop antenna on mine. A 10 inch loop sitting in the window. That is all it wants or needs.

Hello Steve, Regarding SSB, was your design that didn't resolve SSB "low-C" or "high-C"? According to Dave Newkirk, tank circuits where the circulating capacitance has an impedance of 100 to 150 ohms do not "pull" readily. Consequently they resolve SSB reliably. Trust me, Dave Newkirk knows what he's talking about on this point.

Beyond this, when you write about resolving SSB your set must have a tuning rate of 25 to 100kHz per rotation of the tuning knob. Oh yes, you CAN resolve SSB on a set with a high tuning rate, but not so easily.

Finally, your set must be stable, so it MUST be constructed rigidly - solid front panel, rigidly mounted capacitor of good quality and so on.

Whatever circuit you choose, unless you follow the formula above, your set will not perform well. Finally, the real king of regen set construction, James Millen, experimented with various circuits and configurations for about 12 months. At the end he concluded that the circuit wasn't as important as attention to good quality components AND solid mechanical construction.

Finally, among the files for this group, in a folder called "Trawling_RegenRx" you'll find a file (a text file) about the twinplex. This is a collection about observations made here, on RegenRx, about the twinplex receiver. That, I hope, will be a useful source of info for you.

FOR SALE: I have an extra nice Heathkit GD-1B Grid Dip Meter.
Looks better than any I have seen. This was from an estate and it works perfectly.

Comes with the original box of coils containing all the coils plus two extra coils.
The AC cable is in excellent condition and the GDO is fully working.
This was obviously looked after very carefully; 100% clean and no scratches or dents.

Available for $65.00 plus shipping.

(I also have a really nice Millen GDO complete with box etc., for $95.00)

Pictures and details at:
http://af4k.com/testgear.htm

Used the 1951 Novice receiver today. It has two tubes, 12sj7 and 12sl7. I changed to 12 voltage heaters so could use my 13.8 V PS. Using 7x9VDC series for plate supply.

I had built one of these about 50 years ago, don't recall the behavior experienced with this one. The regeneration control interacts with the tuning capacitors. The antenna tuner capacitor interacts with all three. I am using a "band set" and band spread capacitor driven through a vernier.

Am not recalling all these interactions, but maybe that's just my poor memory. I would appreciate any advice or observations.

My next project is a "Bayou Jumper" regen, hoping there are fewer interactions with it.

Very good idea with the hi-C tank, and I would like to try it and see how it works. The ability for a one device detector to receive SSB without distorting or warbling on the stronger signals seems to come from inter-electrode capacitance changes that can influence the tank circuit. Any design that minimizes this will make copying SSB that much more enjoyable.

Rob - and others - you can buy a complete audio amplifier board with several watts of good audio for $2-3 on eBay including shipping. I see a lot of guys wanting to get some $1.69 chip and build their own amplifier. It's a LOT less work and hassle and the things are well made.

I bought several different types to experiment with them, and they do fine.

Rob congratulations on your excellent work with that regen!

The mission was not to buy the project.
The mission was to learn how to build the 716 with the least amount of
room for error
so handing a pile of parts to kids... scouts..... could be guaranteed a
certain degree of success.

I had examined all sorts of audio amplifier possibilities ranging from
discrete components to ICs.
I was chasing the MPF102 / TDA7052 solution only because I found that
the TDA7052 is the IC used in the
HONEYTONE guitar amplifier in the picture here:
http://www.learnmorsecode.com/716/71601.jpg

BUT
after opening up the HONEYTONE and examining the circuit board with a
microscope I found there
is a TL072 opamp and TDA7052 no other ICs so I figure I am not really
doing an apples to apples comparison
with my TDA7052 circuit unless I was to use TL072 as tone control and
pre-amp.

It would have been nice to have the 1W punch amp circuit work as
described but I could not
replicate until all mail ordered parts arrived.... which was just now...
mail brought the monolithic 1Uf C1 caps today.
Noting all the other experiments with 1 and 10 and 20 uF caps brought no
success.
http://www.learnmorsecode.com/amp/1w_Punch_amp_schematic_MPF102andTDA7052.jpg

The mission was not to buy the project.
The mission was to learn how to build the 716 with the least amount of room for error
so handing a pile of parts to kids... scouts..... could be guaranteed a certain degree of success.

I had examined all sorts of audio amplifier possibilities ranging from discrete components to ICs.
I was chasing the MPF102 / TDA7052 solution only because I found that the TDA7052 is the IC used in the
HONEYTONE guitar amplifier in the picture here:
http://www.learnmorsecode.com/716/71601.jpg

BUT
after opening up the HONEYTONE and examining the circuit board with a microscope I found there
is a TL072 opamp and TDA7052 no other ICs so I figure I am not really doing an apples to apples comparison
with my TDA7052 circuit unless I was to use TL072 as tone control and pre-amp.

It would have been nice to have the 1W punch amp circuit work as described but I could not
replicate until all mail ordered parts arrived.... which was just now... mail brought the monolithic 1Uf C1 caps today.
Noting all the other experiments with 1 and 10 and 20 uF caps brought no success.

ahh yes.... LM386...
for a dollar:
http://www.learnmorsecode.com/help/LM386amp.JPG

http://www.learnmorsecode.com/help/cwpmosfet.html

The TDA7052 is a bit more powerful than LM386.
I don't know the exact specifications but I have LM386 and TD7052 amplifiers here that
are hooked up to 10 inch speakers.
The TDA7052 amplifier has a bit more uuuummmpphhh to it.
Not just room filling sound.... been used outdoors ... street filling sound.

I have a pile of LM386 and TDA7052 ICs .
I have been down the LM386 path.
I built the FORREST MIMS book described 741 pre-amp with LM386 audio amp and attached it to a 1N34A crystal radio 20 years ago and heard the world. No selectivity..... just a crowded room full of 50 broadcast band radio stations.
It sounded like a cocktail party in Chinese, Spanish, Russian,French...etc.

Do you have any circuit examples of how you have used the LM386 to amplify RF circuit output?

From: rhulett1@...
Topic: 26787 Message: 26787

I am wanting to build a WBR receiver. Have used manhattan previously but would prefer using a the Far Circuits board. Several threads mentioned abandoning the board and building manhattan style. Has anyone been successful using the board and if so, what modifications were needed to be successful?

73, Curt KB5JO

From: Rob
Topic: 26789 Message: 26789

I'm at the end of my rope with this audio amplifier.

I am sure I am probably doing something extremely simple stupid but I
can not get this IC to play.

The mission was to simply add a very loud ...room filling... audio
amplifier to demonstrate the simplicity
of the experimental 7.16 resonator regenerative receiver circuit:

http://www.learnmorsecode.com/716/VK3YEmodKB3BYT.jpg

more pictures and details here:
http://www.learnmorsecode.com/716/716.html
http://www.learnmorsecode.com/716/index.html

I had found a guitar amplifier circuit that used the TDA7052 IC and I
have years of playing

http://www.jimthorpelivemusic.com/mando/index.html

electric mandolin using a HONEYTONE guitar amp so I thought it would be
a no brainer to
build this circuit:

http://www.learnmorsecode.com/amp/1w_Punch_amp_schematic_MPF102andTDA7052.jpg

but apparently I am not qualified to operate this appliance......

I can not get any audio more than very slight headphone level audio out
of this IC.
I've tried swapping out all sorts of capacitor values and configurations
per advice from
all directions..... but still no amplification.

The data sheet says the TDA7052 "A" has a volume control so I swapped
out the TDA7052

http://www.learnmorsecode.com/amp/TDA7052Avc.jpg
http://www.learnmorsecode.com/amp/TDA7052A_AT.pdf

with a TDA7052A and added the 1uF and 1Mohm volume control and still got
nothing.

and then
as always
unplugged the 716 radio output from the experimental board and plugged
it into the
HONEYTONE amplifier and heard CW blasting.

So
at this time I am offering to mail TDA7052 and TDA7052A chips to anyone
that wants to play with
building an audio amplifier to add to the 716 project radio here.
You keep the chips.... whatever you build.... I just want a picture
and schematic of something that
works so I can build it here and do the scouts projects.

I notice pin 1 is signal ground. Pin 6 is power ground. I don't know whether they are connected or not. Also make sure that the mpf-102 is not hooked up incorrectly, gate and source. Please try and publish results.

Thank you,

Edwin P Carter / WA4YHL

From: Tom Lee
Topic: 26789 Message: 26792

When trying to troubleshoot things like this, it's a good idea to start
by checking dc levels (after precluding obvious things, like wiring
errors). That by itself often reveals where the problem lies.

In this case, note that the MPF102 is a depletion-mode n-channel JFET,
so its source voltage will be above the gate voltage by an amount that
is not guaranteed to tight limits by the manufacturer, but which is
typically a few volts. If the signal driving the gate has a positive dc
component, the FET output could easily be pegged near the supply rail.
To see if that's the problem, just measure the source voltage with the
gate connected to whatever signal source you've been trying to use. If
it's too close to the rails, then you have an idea where your problem lies.

If you are using supply voltages at the lower end of the indicated
range, the probability of a problem increases. Try increasing the supply
to 12V (if you haven't already tried this) and see if things are better.
Also try a different FET (preferably one from a different production
run). You may have gotten one that is close to the edge of the
pinchoff-voltage spec (which exceeds your supply voltage!).

Good luck!

Tom

Rob, make sure you have the pin numbers correct. This is a common problem. Tube are viewed from the bottom and the pin numbers go clockwise from the key or the big pins. IC pins are viewed from the top and go counter clockwise from the dot or notch. This can be confusing especially with wire wrap sockets, wired from below. Also, make sure caps with a "+" sign on them have that side connected to the part of the circuit that has positive voltage on it.

Leonard

To add to the great advice from Leonard, make sure that you've got the FET pinouts right, too. Facing the flat side with leads pointing down, the pins are DSG, from left to right.

Do you have a coupling capacitor between the output of your radio and the the gate of the MPF-102? If you don't then your are biasing the Transistor into saturation with the DC voltage from the output of your radio. I don't see a coupling capacitor on your schematics. If there is none, then check the MPF-102 to make sure it has not been destroyed. If it has, then replace it and put a coupling capacitor in that signal path.

FOR SALE:
Patco Services
model PTS-30
Thermal Wire Stripper.
Excellent for all electrical and electronic work requiring fast and accurate wire stripping.

Used but in perfectly fine, clean operating condition and ready to use....

Retail price - $125.00

Available for $50.00 plus shipping.

I'll have a look in the parts bin. If I can find one I'll wire it up and take a photo.

With few exceptions, tubes and ICs are numbered clockwise when viewed from the wiring(pins) side. Imagine teaching a bunch of assembly techs to count anticlockwise.

All the notes I have seen for this chip show a bias(?) resistor from pin 2 to ground. One manufacturers application note shows a complete audio amp. It has a 5k resistor from TDA5052 pin 2 to ground. The 10k in that receiver ckt you linked should do. Wire it to pin 2 and use a common ground. Do not forget the 100nF cap between pins 6 and 1. Add speaker and power and it should work.

The reference mark on an IC is on top of the chip and indicates pin #1. The pins are numbered down one side and up the other, in a conter clockwise direction, looking at the top of the IC. That's the way they're shown in the data sheets. Just remember to reverse everything when looking at the IC from the bottom.

Don't assume that all transistors have the same pinout. Some are E-B-C, or S-G-D, while others are E-C-B, or S-D-G. Always refer to the data sheets before committing to a hookup.

Leonard

I am not having pinout issues.
Here is the data sheet pinout for the TDA7052A
and the TDA7052 is the same except for the volume control is omitted on
the TDA7052
and is just N.C. not connected.

Have you tried the test circuit in the datasheet? I drew this schematic
looking at the datasheet for reference.

https://scontent-iad3-1.xx.fbcdn.net/v/t1.0-9/13654210_1704731636443934_1172094518084847806_n.jpg?oh=ee60a2475aeb54d238bda9cd6e82b2f1&oe=57F21280

I rooted around in the IC bin last night. Found a LM386 and a couple of ua739's. No 7052s. Where did you get the tda7052s? I used to buy the radio shack IC's that were labeled as "fully functional...may not meed manufacturers specifications" and some of them would not work at all. 73, -Bob ah7i/w4

YES
when I found this in the datasheet
http://www.learnmorsecode.com/amp/TDA7052Avc.jpg
I swapped out the TDA7052 with a TDA7052A and added the 1uF and 1M ohm
resistor.

BUT
since the TDA7052 didn't amplify I wasn't real surprised that the
TDA7052A didn't amplify.

Thats when I figured I share chips and see what everybody else comes up
with them.

The datasheet shows a direct connection to an 8 ohm speaker, with no isolating cap. The input is rated at 100K so it shouldn't be loading the signal souece. Have you considered the posibility that your signal input just isn't large enough? Maybe it needs a preamp. I used an LM386 in my Mk.21 with less that amazing results, until I added a source follower to the input, per David Newkirk. Made a big difference, but not ear splitting. I don't see anything about minimum input signal voltage. With its high input impedance, you should get a hum if you touch your finger to the input terminal.

26804. TDA7052 amp chips tinkerers

Yahoo group: regenrx (2016 — 2017)
Date: 2016-07-12 20:49:13 UTC
From: Rob
Topic: 26789 Message: 26804

I got five tinkerers on the chip offer
so today I mailed a package to each of you containing
1 TDA7052
1 TDA7052A
1 MPF102
2 7.16 ceramic resonators
1 1uF monolithic chip cap
1 .1uF poly cap

the 5 tinkerers:

David Adams
Jimmy D Hill
Bob Liesenfeld WB0POQ
Thang Le
Mike Haydon

should see the package in 3 days.

Sorry I'm late on your offer OM
But if it is possible would like to get in on this…
Been out of town last week, and the week before
and this week been fairly busy, but I would
appreciate the chance to play with these…

Just set up my Pixie to build too, and sent off for
the receiver kit from that latest QST article, so should
be able to do some building this next few weeks :)

Not been paying too much attention to all the mails
of late either, so if you have a charge for this I'll
be happy to chip in OM!

Thanks for doing this

26806. TDA7052 amp chips tinkerers ..... never too late

Yahoo group: regenrx (2016 — 2017)
Date: 2016-07-13 01:17:25 UTC
From: Rob
Topic: 26789 Message: 26806

Its never too late to play radio.

It will be a day or two before I get to the post office again.

My first HF radio was a KNIGHTSMITE.
pretty much based on the PIXIE.

I must say that I am having a lot more fun dabbling with this 7.16
ceramic resonator radio than I ever had with that KNIGHTSMITE.
The KNIGHTSMITE was crystal rock bound at 3.686 Mhz and heard few QSOs
while this 7.16 project heard more than
100 Field Day QSOs ...and other CW contests... and overseas DX. Really
what the hobby is all about.

I am not selling anything here.
I am just trying to learn how to build simple radios that work using
parts that are modern enough that
it can be a cheap and repeatable project we can do with the kids.
Its not enough to build a simple crystal radio anymore.
My local daytime radio stations are not anything children can listen to.
Its all just assholes screaming political conspiracy theories and
preachers and sports talk radio.
No music at all. Just garbage radio.

So I figured its better to chase short wave radio DX stations and CW
when building a kit.

I would say your issue is one of inadequate gain. The Schematic for the Honeytone is attached.

It uses 2 stages of opamp amplification with an overall voltage gain up to 200 (46db), prior to the TDA7052.
Your MPF102 preamp likely has a voltage gain of 2-3 db.

26811. single 9 volt battery supply for TL072 in HONEYTONE amplifier

Yahoo group: regenrx (2016 — 2017)
Date: 2016-07-13 19:16:01 UTC
From: Rob
Topic: 26789 Message: 26811

This schematic shows TL072 opamp but does not show the battery
connection to the opamp.
Which confuses me because I thought the TL072 needed a dual power
supply... plus 9 and minus 9 volts using ground in the middle. The
HONEYTONE amp only uses one 9 volt battery so how did they do that?
Is it merely a matter of connecting the one 9volt battery to pin 4 -VE
...... and pin 8 +VE of the TL072 ?

Rob,

Both TL702 op amps have their + inputs biased to roughly 4.5V using the voltage divider resistors on the upper right hand side of the schematic. Their outputs are tied (through resistors) to their - inputs; hence their outputs are biased to the same 4.5V since the - inputs track the + inputs to a very small voltage delta.

I suspect the whole circuit including the two TL702 operate off a 9V power supply.

Thang Le

It can be done. My RAL receives SSB with better fidelity and clarity
than any modern receiver I've used. It really sounds good. AM is so
so. I opened the audio amplifier for higher frequency response, as it
was designed to roll-off above 1300 cycles. The detector is a 6D6 with
screen and suppressor grids tied together to a pot for regeneration
control.

Here is a reworked image of the honeytone schematic.
I had to enhance the printed text to get a clear component value.
note the component we are discussing is the DUAL OP AMP TL072.

http://www.learnmorsecode.com/amp/honeyrule.jpg

In this image there are 3 colored resistors....
56k purple
47k green
1k red

can you tell me where would I attach a wire to this voltage divider
network to feed pin 4 (VCC-) of the TL072 op amp?

I'm sure I messed up that logic real good.

I definitely am missing something here......not knowing where pin 4
(Vcc-) gets attached to the 9 volt battery or if it needs to be attached
to a voltage divider pair of resistors.

26816. Fwd: [regenrx] My next project...a twinplex?

Yahoo group: regenrx (2016 — 2017)

Attachments: 2 described; binary payloads are missing from this source WARC

Hi,

I want to share a recent regen receiver design.

I attach schematics of two versions of an all transistor receiver that I built recently. The two versions differ in how the emitters of the pair of regeneration detector transistors are wired: in the simpler version, a variable resistor between 5 K ohm and 20 K ohm (to + supply line) should work fine. I prefer the other version, which uses a current source.

The receiver as built resolves SSB and CW signals well. If I build the circuit again, I would want to make the first stage of AF amplification be an emitter follower design. The AF feedback circuit was all guess work; I settled for what seems to work. I'm certain it's not optimized. I put in 5 stages of AF amp because I believed the smaller gain of each stage (due to the lower bias points that are necessary in this 1.5 V PS design) requires 5 stages! The last stage uses a PNP transistor because I want to use a grounded output audio jack (negative ground goes to metal box). In particular, I like the simplicity of the "Franklin" oscillator-regen design (requiring a single inductor), plus the double-diode "voltage doubler" envelope detection circuit.

Subject: Re: [regenrx] My next project...a twinplex?
To: regenrx@yahoogroups.com

It can be done. My RAL receives SSB with better fidelity and clarity than any modern receiver I've used. It really sounds good. AM is so so. I opened the audio amplifier for higher frequency response, as it was designed to roll-off above 1300 cycles. The detector is a 6D6 with screen and suppressor grids tied together to a pot for regeneration control.

Richard, AA1P

On 07/06/2016 06:03 PM, Doug Hancock nzerowva@... [regenrx] wrote:

The twinplex will be just as bad on SSB as the rest of them unless you use very light tank coupling. Just enough to get good oscillation. If you want a solid SSB performer, check out a solid state regen I built a few months back. http://www.theradioboard.com/rb/viewtopic.php?f=4&t=6891

<kc2siz@gmail.com[regenrx]> <regenrx@yahoogroups.com>
<regenrx@yahoogroups.com> wrote:

I've built several regens, both solid and hollow state. They all worked,
some better than others, but none of them have done as good a job as I'd
like at demodulating SSB signals. I'd really like to remedy this.

A friend of mine recommended that I build a twinplex for this purpose. Are
there any other circuits you'd suggest? I don't care whether it uses tubes
or transistors so long as it's a strong performer on SSB.

26817. Re: [regenrx] single 9 volt battery supply for TL072 in HONEYTONE amplifier 2

Yahoo group: regenrx (2016 — 2017)
Date: 2016-07-14 07:26:43 UTC
From: J Ed
Topic: 26789 Message: 26817

Most dual op-amps have identical pinouts and the circuits used are somewhat standard. You'll see the same circuits in many different devices.

Anywho, the opamp VCC+ and VCC- are connected to the +9v and 0v points, respectively. Then one of the inputs are referenced to a voltage that's roughly 1/2 VCC. That's where the 56K, 47K, and 1K resistor come in. They float the input at 1/2 VCC and make the opamp think it's hooked up to a +/- 4.5v supply. Notice that in dual supply circuits, the inputs are all referenced to ground.

26819. 716 regen then LM386 pre-amp then TDA7052 plays CW

Yahoo group: regenrx (2016 — 2017)
Date: 2016-07-14 08:27:25 UTC
From: Rob
Topic: 26819 Message: 26819

I got the TDA7052 to play CW at good comfortable audio level by adding
an LM386 kit as a pre-amp.

http://www.learnmorsecode.com/help/LM386amp.JPG

so KF8ZN made the winning call here.

I've been down this path before.....
used the LM386 kit to pre-amp a circuit then built a transitor pre-amp.
http://www.learnmorsecode.com/help/cwpmosfet.html

I would still like to see what everybody else builds with these TDA7052
chips.

It was very discouraging to spend weeks kicking the tires on this one
but now that I heard CW
without the guitar amplifier I can move on.

Another regenerative receiver with a singe coil is a circuit which is based upon the MC1648 VFO IC. It also has the two transistor emitter coupled oscillator, which is a very versatile oscillator circuit.

Schematic:

Rob,
No worries! That's how we learn.

I have some TL072's I plan to use as the front end for the Amp you are sending. 1 tlo72 configured with a gain of 100x (40dB)

It's all in the math.

50 microvolts (S9 on a properly calibrated S meter)
equals -73dBm (note: MINUS 73dBM)

1 watt= 30 dBm

SO.... Ballpark 100 dB of required gain from antenna to speaker.

Rob,
I also feel compelled to note that the LM386 circuit you are using is the most common, and NOISIEST, out there.

I encourage all to try the circuit referenced below.

I have built it, and can vouch for very stable gain of 50dB.

All IC Audio Amp http://www.qsl.net/qrp/acc/lm386.htm

All IC Audio Amp http://www.qsl.net/qrp/acc/lm386.htm LM386 is very popular IC also in Japan. It is used in Radio receiver. The power of it (500mW) is enough for the personal use. But sometimes, the gain of it (40dB) is not enough.

A bit dated, but golddust in their time!
I built a German kit which worked well.
Circuits on the web, which would still
be "competitive" for CW and SSB.

26832. Mk.22

Yahoo group: regenrx (2016 — 2017)
Date: 2016-07-16 19:18:18 UTC
From: Leonard Meek
Topic: 26832 Message: 26832

Ever since I was a kid and submini tubes were being invented, I've wanted to build a radio using them. My first real attempt was my Mk.19, a 3 tube MW regen. It worked surprisingly well at first, but started to degrade. It may have been the batteries or the proxomity tubes I was using. Anyhow, I decided to build a better radio, using 5 hearing aid tubes. From the start there were problems, mainly with my eyesight but also with the small size of everything. It was like trying to thread a needle while wearing boxing gloves. I used a mini output xfmr that had a Z of 2500 ohms imto an 8 ohm speaker. But the 5672 needed a 20K ohm load. I had a 45 ohm speaker that would bring the load Z up to 15K ohms, not enough but better. The performance won't make any headlines, and it definitely shows the limitations of my abilities. I'll post a schematic of what I have so far.

Can you take pictures of the insides of this radio?
I got the schematic.
Thank you.

26840. 716 regen then LM386 driving speaker..... no TDA7052

Yahoo group: regenrx (2016 — 2017)
Date: 2016-07-17 05:38:34 UTC
From: Rob
Topic: 26819 Message: 26840

I got the 716 regen then LM386 driving speaker..... no TDA7052
based on the JF10ZL circuit:
http://www.qsl.net/qrp/acc/lm386.htm

I used a 5K pot where the volume control is done by pin 1.
JF10ZL says to use 3 to 1,000 ohms to control the volume.
I didn't have any variable resistors smaller than 5K.

http://www.learnmorsecode.com/716/lm386.html

I definitely did get the desired result.

OUTSTANDING!

That Gentleman's webpage contains a lot of good info!

How high in gain (or low in resistance) are you able to go without instability?

If you would post a photo of the actual build I'd appreciate it

Brilliantissimo, Leonard!

All it needs now is more tubes, fewer Rs and Cs
and I could probably build it...

We all tremble at the fate of the Yahoo newbie
who dared to momentarily exterminate you...

I will be examining that measurement today.
It was some midnight science to make it work and it did
have a threshold it would cross that would scream a really
high pitch screeching mixed with the CW audio.
I thought that perhaps I should record it and share that recording with
you wizards and
someone would explain what I needed to do to fix that screech.
My first thought was that there was an RF choke solution somewhere in
the audio chain.

Perfomance is not great, but it's close to the prediction based on the measured tube characteristics. The total filament current is about 0.5 amps and pulls the battery voltage down to 1.1 volts. Total plate current is about 2.2 mA. I haven't tried it with my bench supply but I suspect it would work a little better, if it didn't pick up AC hum. I don't think I would attempt this kind of construction again. My eyesight can't handle it. Beats me how guys can do surface mount stuff.

26846. TDA 7052 Amp 716 circuit regeneration resistors and pots

Yahoo group: regenrx (2016 — 2017)
Date: 2016-07-17 19:56:20 UTC
From: Rob
Topic: 26846 Message: 26846

PICTURES and detail here:
http://www.learnmorsecode.com/716/716.html

The original circuit was this one:
http://www.learnmorsecode.com/716/ceregen202.jpg
Note the chain of resistors labeled REGENERATION
went from the PLUS VOLTS rail to
220K resistor then
50K pot then
4.7M resistor

I had ZERO audio regeneration and heard no radio stations or CW when I
had the
220K resistor in line.
So I removed the 220K resistor and then heard CW.

Note that the 50K resistor goes from PLUS VOLTS to GROUND with the tap
in the middle.
I did not have a 50K pot so I used TWO 20K pots in series with the tap
in between the
two pots.

I got CW reception using both 20K pots set at 7K ohms
then found that replacing both pots with 5.6K resistors heard CW
so I left out the bottom 20K pot and now use 10K of the top pot:

http://www.learnmorsecode.com/716/VK3YEmodKB3BYTv2.jpg

Its all just an experiment for me.
I'm still learning why it works.

What do you mean by "JUST" a transistor bias circuit?

This image and labels were made by the circuit author:
http://www.learnmorsecode.com/716/ceregen202.jpg
but was condensed to fit..... so I'm wondering if I mucked up the labels.

I'm a hobby electronics dabbler...not an educated electronics engineer
....so
if the label REGENERATION is wrong I would like to know.

Anyone else here think REGENERATION is a mis-label that should say
TRANSISTOR BIAS CIRCUIT?

Hi Rob,

the 220k resistor and 50k pot control the bias of the transistor. So,
the pot controls the regeneration of the detector circuit which
essentially is a colpits oscillator. It starts to oscillate as soon as
it gets enough base current. The pot is correctly named the regeneration
control.

Regarding the point that the circuit adjusts the bias for the transistor, I think the word, "just" means this circuit is often seen. He might have written, "this is a commonly used circuit". As for labeling this pot with the words, "regen" or "regeneration" - that is an excellent choice. That word has a specific, well understood meaning. Changing the bias controls the amount of regeneration or feed-back.

I hope this explanation helps.

Les

Easy Rob. I felt the sting here too. Just remember anytime you actually do something a 100 "experts" will pick it apart. There is a reason for that and when you figure it out you will realize why and use that for assurance that you are probably on the right track and will just smile inside and carry on. I've had a lot worse and lived. Interesting project. donVe3LYX.

I don't remember what group it was, but someone said "you can switch the drain and source".
Some you can, but there are a lot that are not symmetrical.
Just had to throw that in here.

Hi Dave,

I'm very intrigued by your statement. Do you have a list of part numbers of JFETs that aren't built symmetrically? I haven't encountered one that wasn't intended to be symmetrical (it takes extra steps to make an asymmetrical JFET), so I'm eager to learn something new.

Thanks!

Thank you very much for the links, Phil. I am a bit puzzled, however, because I've used the J310 for a long time as well, and all the ones I've ever checked have been symmetrical (within small variations that are to be expected). I've exploited that symmetry to use the standard feedback trick to linearize them when used as voltage-controlled attenuators, and I've never had to trim the feedback resistor more than an amount roughly equal to the resistor tolerances.

I just checked the Fairchild datasheet, and it contains an explicit statement to the effect that the source and drain are interchangeable. I also see that a Clifton Labs webpage (http://www.cliftonlaboratories.com/jfet_variation.htm) contains measurements showing essentially identical V-I curves with source and drain interchanged.

Maybe you're thinking of another part, or perhaps some manufacturers make their J310s differently? Very mysterious...

Tom

Hello Mike,

First, my reply is based on the manual only. I have never owned a RAK (or RAL), and I have never measured the parameters that interest you. So - my reply depends on my understanding of the circuit - in this case for the RAK-5.

Looking at the two supplies (90 & 180V) I believe you are correct - connecting power to the 180V should supply the detector screen via dropping resistor - R117. That this connection is correct can be confirmed by checking the screen voltage against the value in the manual. (I'm sure you know this already!) Apart from a bypass capacitor, the only circuit supplied by the 90V battery is the detector screen grid (and of course the potentiometer in that circuit.)

I follow the logic of adding the current for the plate and screen supply lines. I believe you are correct. You can confirm this by monitoring the current in the B+ line between your PSU and the set. (Again, I believe you know this already).

I feel somewhat embarrassed to answer this posting, because I'm not speaking from actual measurement - only from reading the circuit diagram/manual (as you have done already). So I'm simply supporting your own (reliable) observation.

Les

26864. Using a Darlington pair as an AM detector.

https://circuitsalad.com/2015/01/22/variation-on-junk-box-bipolar-regenerative-receiver

Darlington pairs used as an AM detector, are very suitable for using it in TRF and regenerative receivers, because they have a very high input impedance. This allows to connect them onto the top, or hot end, of any tank circuit. Coil taps or link coils are not necessary anymore. Very useful when using a Q-Multiplier with two-terminal coils only, think about the Colpitts and emitter-coupled oscillator topologies.

In a Darlington circuit the first transistor acts as an impedance converter, while the second transistor is the actual AM detector in which the collector has been shunted to ground for RF signal by a cap of 10 nF.

But how is the demodulation performance of Darlington detectors on higher frequencies in the shortwave range? This provided that HF-capable transistors like BF494, BF495, BF240, etc. are used.

From: J Ed
Topic: 26864 Message: 26865

If biased just at cutoff, should be okay; Assume the emitter current of the second transistor is 5 mA, the emitter resistance is 5.2 ohms. If you assume the HFE of each transistor is 150, the input impedance of the pair is going to be 117K in parallel with any biasing resistors. You'd want to bias the bases at 1.0 to 1.1v, just so the bases are just below conducting.

It's also possible to make a base-leak detector. Because it depends on conduction during the positive cycle, I'm not quite certain a pair would be better than a single transistor.

In either case, I'd choose a JFET over a bipolar transistor.

FWIW,

A not so obvious problem with using Darlington pair transistors is that the tradeoff for the high gain is bandwidth.

It is true that the gain of the transistor pair is essentially the product of the Betas of the two transistors, but the input capacitance is the sum of the capacitance of the first transistor, and Beta x the capacitance of the second transistor.

Darlington devices are not fast.

If you use a FET for the first stage you can overcome this somewhat and get the high impedance you want.

Best regards,
Jim Scott

Subject: [regenrx] Using a Darlington pair as an AM detector.

The following topics below are about regenerative receivers in which a Darlington pair is used as a (regenerative) AM-detector which is connected onto the top of a tank circuit.

* http://theradioboard.com/rb/viewtopic.php?f=4&t=4037 "Are Darlington pairs suitable for using in regen receivers?"
* http://theradioboard.com/rb/viewtopic.php?f=4&t=7063 "SW REGEN USING BASE-EMITTER AND MILLER CAPACITANCE FOR FEEDBACK"
* http://oernst.f5lvg.free.fr/rx/vv1/vv1.html "RECEPTEUR A REACTION SPECIAL BLU"
* "Junkbox Regen" at https://circuitsalad.com/2014/12/06/another-excellent-performing-regen-circuit-coming-shortly

* "Variation on Junk Box Bipolar Regenerative Receiver" at https://circuitsalad.com/2015/01/22/variation-on-junk-box-bipolar-regenerative-receiver

Darlington pairs used as an AM detector, are very suitable for using it in TRF and regenerative receivers, because they have a very high input impedance. This allows to connect them onto the top, or hot end, of any tank circuit. Coil taps or link coils are not necessary anymore. Very useful when using a Q-Multiplier with two-terminal coils only, think about the Colpitts and emitter-coupled oscillator topologies.

In a Darlington circuit the first transistor acts as an impedance converter, while the second transistor is the actual AM detector in which the collector has been shunted to ground for RF signal b! y a cap of 10 nF.

But how is the demodulation performance of Darlington detectors on higher frequencies in the shortwave range? This provided that HF-capable transistors like BF494, BF495, BF240, etc. are used.

When using a Darlington pair as an AM detector, the collector of the first left transistor should be connected to the supply rail, in stead of connecting it to the collector of the second right transistor. An improvement is also to put a resistor with a value between 10k to 100k between the emitter of the first transistor and ground. Purpose is to discharge the base emitter junction of the second BJT and to allow flowing sufficient current through the first BJT.

At http://electronics.stackexchange.com/questions/77520/resistors-within-a-darlington-transistor http://electronics.stackexchange.com/questions/77520/resistors-within-a-darlington-transistor it is explained why this resistor is needed:

Those resistors are to speed turn-off. The base-emitter junction has some capacitance, which is made apparently larger in an inverting amplifier configuration by the Miller effect. To turn the transistor off, this capacitance must be discharged.

When the base drive is removed, there is no path to discharge this capacitance of the right transistor, because the reversed-biased base-emitter of the left transistor prevents it. These resistors provide a path for this discharge current.

I think this also true for using darlington pairs as detector on higher shortwave frequencies. Think about the negative half of the RF signal cycle.

You can also let the first transistor of a Darlington pair function as an infinite impedance detector, put a capacitor of some nF between the emitter and ground of this transistor and shunt it by a resistor of 100k. Then the second transistor only functions as an AF preamplifier.

Hi Jim,

There is definitely a tradeoff between gain and bandwidth for a Darlington. However, it's not because the input capacitance grows (it in fact goes down -- you have two capacitances in series; it can't go any other way). It's because the collector current of the first transistor is the base current of the second, so the first transistor is starved for current. Transconductance is proportional to current for a bipolar, so gm will go way down, but the capacitance only does so for a while (then it bottoms out). So ft plummets. Plus, the low current means that it slews poorly, so there's a large-signal limitation that compounds the small-signal effect.

A more subtle problem is that the capacitance of the second transistor reflects as a negative resistance when viewed from the base of the first. That can lead to oscillation. This phenomenon explains why you see so many "base spoiling" resistors in stages where a follower is driving a capacitive load.

--Cheers,
Tom

A Transistor operating in current starvation mode can be used as an infinite impedance detector in a TRF or a regenerative receiver. See these two regenerative receivers at http://oernst.f5lvg.free.fr/rx/14mhz/rx1v1_14mhz.htm
http://oernst.f5lvg.free.fr/rx/14mhz/rx1v1_14mhz.htm and
http://oernst.f5lvg.free.fr/rx/0v2/0v2.html http://oernst.f5lvg.free.fr/rx/0v2/0v2.html in which a separated detector stage is used which is biased in current starvation mode with an Ic of a few uA. Here general purpose transistors like the BC547 are used in the detector stage, in stead of using RF transistors. I think that when suitable RF transistors are used in a current starved infinite impedance detector, the detector would also be able to detect higher shortwave frequencies and even VHF frequencies. Another example of such an infinite impedance detector is at http://www.qsl.net/g3oou/solidstatecircuits8.html
http://www.qsl.net/g3oou/solidstatecircuits8.html

Schematics of current starved infinite impedance detectors:

http://www.qsl.net/g3oou/_wp_generated/wpb1e04994_06.png

How would a poorly slewing transistor due to the current starvation be noticeable when receiving shortwave stations at higher shortwave frequencies, or will the sensitivity be reduced?

@Tom:

"A more subtle problem is that the capacitance of the second transistor reflects as a negative resistance when viewed from the base of the first. That can lead to oscillation.

This phenomenon explains why you see so many "base spoiling" resistors in stages where a follower is driving a capacitive load."

This is the capacitive voltage divider which is part of a Copitts oscillator, but it is hidden as internal parasitic capacitances inside the Darlington transistors.

A Belated Thanks Rob
For one reason or another I have not gotten around to tinkering yet :) Mowing weeding and cleaning windows :) Anyways, I'm sorry I did not post this last week, got my goodies from Rob and don't think I have anything I HAVE to do tomorrow so will look up the data sheets. I do know where my breadboard with PS resides, so I am running out of excuses.
I can look through some of the group's old emails, but has someone an idea of where I should start? In other words, what have you done, and would putzing with your circuit provide me with some education :)
I guess that would be answered yes… :)
IF I have anyone's attention yet, I'm thinking of a possible kit like Rob's. Not to be in competition Rob, just bought a bunch of those 3 lead TRF ICs, and would like to see some results working with them…
Would there be any interest in those three legged ICs??? Can't imagine how they get so many items into one of those little things, that look like a 2n2222…
Be glad to help sponsor a tinkerer's kit if anyone has a hankering to play with this IC. Let me know what I should include if I do do something like that.
Thanks again Rob.
73 fer now everyone

DID YOU GET TA7642 ICs ??????
http://www.learnmorsecode.com/amp/TA7642app.jpg

I got a pile of them to play this same game!..... figure out something
to kit for the kids... scouts.

I landed on the 7.16 ceramic resonator project because it gave me real
world 40 meter CW
not just local broadcast radio stations.... which around here isn't too
kid friendly..... no music stations....
just preachers , fear mongering political garbage, and talking about
sports radio. Absolutely useless crap.

You build whatever piques your interest.
I sent the TDA7052 chips to see if anyone could build a room filling
loud audio amplifier
to play the 716 circuit. I'm just looking for an example of something
that works... after I couldn't
get the loud audio results here.

Today's experiments here are with TL431 audio amplifier circuits:

Darlington feedback pairs are also used in monolithic amplifiers intended for microwave purposes, see https://www.minicircuits.com/pdfs/MAR-2SM+.pdf
https://www.minicircuits.com/pdfs/MAR-2SM+.pdf for example.

Here is a synchronous oscillator in which a Darlington pair is used to demodulate the 10.7 MHz IF signal. TUN stands for a universal transistor like the BC547. T1 forms a high-Z input buffer, while T2 is the actual synchronous oscillator. To improve the performance, I would put a resistor of 10k between the emitter of T1 and ground.

I just uploaded photos & schematic of my version of Rob's (Kyoritsu) version of the Heath GR-81. It works quite well right now but doesn't do well on SSB or CW. At present it uses a 6DJ8 detector and untuned RF amp with an MPF-102 booster. The RF gain is unsat and will be replaced with an ant attenuator in the input. At the risk of completely screwing it up, I'm going to replace the 6DJ8 with a 6U8A, with the pentode section as the detector and the triode as a GG amp. I'll see if I can get by without the booster amp. It tunes from about 500KHz to over 20MHz with 7 plugin coils. As with all my chassis mounter speaker sets, there's a certain ammount of accoustic feedback, but it's controlable. Watch this space for further developments.

I just uploaded my latest revision of my version of Rob's (Kyoritsu) version of the Heath GR-81. I made a few changes in the front end that seem to work pretty well. I changed the 6DJ8 to a 6U8A. There didn't seem to be much advantage to a variable cap on the tickler coil so I deleted it. I changed the 12AX7 to a 5751, which reduced the accoustic feedback. SSB is much clearer now, although a little drifty. One remaining problem is the panel. It's 1/8" plexiglass with a thin sheet of aluminum backing, and it flexes enough to affect tuning. I'll play with it for a whille before moving on to my next project.

This might be THE final circuit to share with newbies.

The 716 regen project
http://www.learnmorsecode.com/716/index.html

gelled into the repeatable circuit
http://www.learnmorsecode.com/716/etch/001drawing.jpg
that was etched
http://www.learnmorsecode.com/716/etch/050done.jpg
http://www.learnmorsecode.com/716/etch/index.html

and proved to work just like the wirewrap version
http://www.learnmorsecode.com/716/716.html

when plugged into an audio amplifier
so then experimenting with TL431 ICs made
some progress with minimalist audio circuits:
http://www.learnmorsecode.com/amp/tl431.html

the last experiment was with a VU2PPP circuit that added a 2N2222 to the
TL431
http://www.learnmorsecode.com/amp/tl431VU2PPP00.jpg

which gave pretty good desk top audio.
and
I heard F5IN in France:
http://www.learnmorsecode.com/amp/f5inqso.mp3

so I'm thinking this audio amp circuit should be knitted into the
716 etched circuit to build the complete receiver on one PCB.

All I gotta say is "WOW".

short answer:
716 receiver:
http://www.learnmorsecode.com/716/VK3YEmodKB3BYTv2.jpg

connected to TL431 audio amp
http://www.learnmorsecode.com/amp/tl431VU2PPP00.jpg

long answer:
Yes.... its a mess of stragles .... a picture here... an email there......
but
its definitely all laid out real neat so anyone can repeat these
experiments.

There were two halves of this experiment... first was a receiver circuit
and the one that
worked for me using WIREWRAP and then replicating it with printing a
circuit board was this one here:
http://www.learnmorsecode.com/716/VK3YEmodKB3BYTv2.jpg
at
http://www.learnmorsecode.com/716/716.html

Noting the two parallel 10 Megaohm resistors were replaced with one 4.7
Megaohm resistor
on the printed circuit board seen here:

http://www.learnmorsecode.com/716/etch/index.html

Note also that all of my 716 experiments fed their output into a store
bought 9 volt guitar amplifier
that was based on TL072 preamp and TDA7052 ICs.
sooooooooo.....
next came audio amplifier experiments.
I failed to produce acceptable audio using the TDA7052 ICs so that
distraction took me a month
to give up on before offering TDA7052 chips to anyone who wanted to try
to make room filling
audio come out of the 716 circuit.
http://www.learnmorsecode.com/amp/honeyrule.jpg

Then I played with LM386 ICs
http://www.learnmorsecode.com/716/lm386.html

And then I played with TL431 ICs
http://www.learnmorsecode.com/amp/tl431.html

Definitely concluding that the original 716 circuit was producing
enough audio output to drive the guitar amp but barely enough to

drive a TDA7052 or LM386 or TL431 without having at least one more
pre-amp circuits in front of those ICs.

And it wasn't just me.
One of my 716 "tinkerers" reported low audio results until adding
multiple amplification stages.

So my last experiment was with the VU2PPP audio circuit:
http://www.learnmorsecode.com/amp/tl431VU2PPP00.jpg

which is the bottom half of this web page:
http://www.learnmorsecode.com/amp/tl431.html

I am not an electrical engineer.
This is strictly amateur hobby radio electronics dabblings in
electronics witchcraft......
so if anyone wants to tell me to add or change something here because
components will burn then I'm all ears.

The mission here was to simply find a minimalist parts 40 meter
CW receiver circuit that could be repeated with newbies... kids.. scouts.
And so far......
this is looking like it works.
For me...hearing France seconds after applying power to the circuit
just says it all.
It was "desk top" loud enough in an 8 ohm speaker.
I would still like to have louder ....because I am a few feet away
from a noisy air conditioner.
But overall this was a successful endeavor.
I may examine changing a few resistors to get more volume.
If anyone has any advice there I would take it.

IF
nothing gets changed
THEN
I do expect to merge the existing 716 circuit with the existing VU2PPP
audio circuit for a one board build.

FWIW: I built the "Junkbox Regen" described on Ray Ring's site and it works very well. It uses a couple of 2N222A transistors in Darlington arrangement.

26885. Can I substitute ETHYL LACTATE as heatless toner transfer solution

Yahoo group: regenrx (2016 — 2017)
Date: 2016-08-08 01:44:57 UTC
From: Rob
Topic: 26885 Message: 26885

I just finished the copper layout process in GIMP for the TIP31 TIP32
mod for the SM7UCZ push/pull experiment:
2N3904-6 circuit:
http://www.learnmorsecode.com/amp/SM7UCZamp2.jpg
board to etch:
http://www.learnmorsecode.com/amp/SM7UCzamp1.jpg

revised for TIP31-2 :
http://www.learnmorsecode.com/amp/SM7UCZampTIP31.jpg
http://www.learnmorsecode.com/amp/SM7UCzamp1TIP31.jpg

All just a stack of comparison experiments:
http://www.learnmorsecode.com/amp/tl431.html

I stumbled across two methods of getting the printer toner to release
off of paper
and transfer onto copper clad board without using heat like an iron or a
laminator.

One method said to spray white lacquer paint onto the copper and let it
dry about one minute
and then simply press the laser printed circuit onto the painted copper
board.
Then peel away the paper and it leaves the toner stuck to the PCB.

THEN ... lightly rag wash the PCB with alcohol and the white lacquer
paint will rub off
leaving the toner image.
Stunning successful results on youtube:
https://www.youtube.com/watch?v=0dpCi9kgpuw

The other heatless transfer method was much more scientificly explained

https://www.youtube.com/watch?v=HBIxvwZ_0og

that alcohol has no affect on toner while acetone easily washes away
toner so
by mixing 8 parts alcohol to 3 parts acetone you get a solution that will
SOFTEN the toner enough to make it sticky but not dissolve or blur.

So this got me wondering just what is acetone?
How toxic is it to play with acetone?
And concluded that acetone is some pretty benign stuff compared to other
solvents here.

I have some brush cleaner labeled DANGER POISON EXTREMELY FLAMMABLE
that contains:

ACETONE
METHONOL
METHYLENE CHLORIDE
TOLUENE
XYLENE

warning of cancer and all sorts of nasties.

I have another solvent screaming how green and better for the environment it is
KLEAN STRIP GREEN
Natural Multi Purpose Solvent
which warns CAUTION:COMBUSTIBLE,EYE IRRITANT

instesting.... not a poison?
which contains ETHYL LACTATE

so this has me wondering if I can actually dilute the ETHYL LACTATE..... mix it
with alcohol to do the same thing as the ACETONE/ALCOHOL on youtube heatless transfer.

but I'm no chemist.

Can I mix this ETHYL LACTATE with alcohol? water? alcohol that comes mixed with water?
Just for giggles..... lets say I do come up with a mixture of ethyl lactate mixed with alcohol thats DOES actually do the
toner transfer the same as 8 parts alcohol with 3 parts acetone and I get nice toner circuit stuck to copper board.

What happens next when I dunk the copper board into muriatic acid and hydrogen peroxide?
Does the ETHYL LACTATE in the toner go nuts and burn off the board?

Hi,

someone have ashematic for multiband receiver with ta7642 ic?
I've intersted to lw/mw/and low band SW .
If you have also a front end schematic suitable for this bands are welcome..

Many thanks
Roberto iw2evk

I just sent off for 100 of those little ICs
When I get them I'll be happy to share
I hinted at this in my thanks to Rob for
the goodies he sent our way and thought
this chip would be also fun to play with.

I saw an add for one IC for $7 something,
or I could buy 100 for $4.45 and $1.50 for
shipping and handling :) Hard decision to
make… So, don't have too much invested
in the project.

Of course coming from China it will take a
couple of weeks to get here :)

73 Guys and thanks for all the food for thought
Bill

I too will look forward to seeing anyone’s
results with playing with the TA7642 :)
Would ask for some myself, but I have
more time then money (I hope) :)
I did see some youtube results of this
IC and it does look promising.
73 fer now

OK guys.....so far I have two tinkerers and one fire hazard.
Hey Cecil.... can I throw a couple your way and you see if mine are as
bad as yours were?

My interest here is learning what works.
So if anybody does build anything and can show and tell what works...
and just the same..what to avoid.....
I have no problem making this donation to the educational cause.

I've learned more in the last year from group efforts than I did in my
first 50 years of tinkering on my own.

I'm going to try to figure out this guy's schematic.
If anyone already has it then please share.

Some time ago I built the entire TA7642 chip out of discrete components and it worked quite well. See attached photo.

Not sure why, but it needed a 9 volt supply rail instead of the usual 1.2 to 1.5 volts to function properly.

That's a very interesting observation, Udo. But I believe they are connected the correct way round. I had a bag of 2N2222's which I used for the project, and the pinouts for these transistors differ from the more common BC547 variety.

That's the reason that they look like they have been inserted on the board incorrectly. Please refer to the attachment for the pinout details.

26904. The ECH81 plus ECL82 Regenerodyne

Yahoo group: regenrx (2016 — 2017)
Date: 2016-08-09 16:52:53 UTC
From: Prof. Arnaldo Coro Antich
Topic: 26904 Message: 26904

The ECH81 ¨frequency converter stage¨ will benefit from a very simple RF signal attenuator in parallel with the link coupling. A 1000 ohms good quality carbon track potentiometer will work fine in that position. You can even use a wirewound 1000 ohms potentiometer because the action of its inductance will be almost nothing at the operating frequency.

The ECH81 may be used as an UP CONVERTER, if you want to build an AM Broadcast Band Receiver using the Regenerodyne circuit...10.000 megaHertz crystal will push up the 530 to 1700 kHz AM broadcast band to 10530 to 11700 kHz still an acceptable range for a well built regenerative detector But it would be a better choice to use a 3.0 megaHertz crystal and tune the regenerative detector from 3530 kHz to 4.7 mHz , although this choice will require very good shielding of the regenerative detector...in order to avoid feedthrough of signals of stations operating within the 3.53 and 4.7 mHz range, especially during local evening hours ...

When asked by a local radio amateur what if any advantage the AM broadcast band up conversion set up had, I explained that the dial of the regenerative detector can be easily calibrated to show 530 to 1700 kiloHertz... Tuning of the AM stations can be as sharp as one sideband by taking the regenerative detector very close to the point of oscillation, making it very selective.

No rare or unobtanium parts are involved !!!

Hi Bob,
very interesting. I did a little search and found at wikipedia that
there are two different kinds of 2N2222 around. Some of them are marked
P2N2222, and those have the same pinout as the BC547.

From: b_weeber@...
Topic: 26904 Message: 26907

Hello Arnie

Some thoughts about the idea:

- An upconverted range has a smaller frequency ratio, therefore the regeneration has to be adjusted less often
- on the other side a fixed regenerative if seldom has to be touched
- an if frequency around 2-3 MHz offers a good ratio, little influence between regeneration and frequency,
good selectivity and sound in the same time
- A lower frequency can be calibrated more accurately, important is the isolation between antenna
and the regenerative stage
- Harmonics of the reception signal are breaking into the if and can cause birdies
- Crosstalk between a regenertive stage in autodyne mode and the mixer are another source of birdies,
at least the regenerative detector has to be in a different tube
- a 455kHz if is too narrow for a good am sound

Feel free, to use this as a source for your own ideas:
http://www.b-weeber.de/bilder/Konverter-Superhet/ECH81_converter_superhet.zip
http://www.b-weeber.de/bilder/Konverter-Superhet/ECH81_converter_superhet.zip

About 2/3 of the circuits have been built and are working. Sometimes the amplification was too little (for my purpose), then i tried to overcome this by reflexing the signal.

Best regards,

Bernd

Dear amigo :Your circuit diagrams are very interesting ... but the need to use quartz crystals of the same or very near the same frequency for a ladder type filter is impossible for me to put in practice, because there are no suppliers of such crystals here.

When I recycle equipment , first parts that go to the treasure chest are the quartz crystals and the computer clock assemblies !!

I fully understand what you explain about the many interacting elements to be taking into consideration when implementing the Regenerodyne receiver concept.

A crystal controlled front end , using well designed input signal attenuator and a bandpass two sections (dual tuned) input filter feeding the also very well built regenerative detector will provide excellent results.

Sure, there is no AGC , and the ¨bandwidth¨ control is fully dependent on reaching the ideal critical operating point for the regenerative detector.

Perhaps for this reason is that I prefer to use a tetrode or pentode vacuum tube detector applying the regeneration control by means of the screen grid voltage. Feeding the regeneration control with very well regulated voltage. With the 6AK5''s a very smooth transition between almost no regeneration and reaching almost the point of oscillation is what makes this detector circuit so attractive to radio hobbysts that enjoy tweaking controls that really do their job.

When very near the oscillation point, one can achieve a very high degree of selectivity, actually on the AM broadcast band it is possible to separate the two sidebands...and that requires around 3 kiloHertz selectivity !!!

** but the need to use quartz crystals of the same or very near the same frequency
** for a ladder type filter is impossible for me to put in practice

Then just leave the crystals away, like i did with the "ECH81_v3.jpg". With this circuit i recognized, how strong cross talking can be within one tube. With or without crystal filter, there was no audible difference. After using two seperate ECH81, with a bw of 250Hz the cw-filter was almost too selective.

Standard crystals here are very cheap, one piece ~20 cent. Hope, in your country this begins to change now. If there is a electronic supplier, then maybe it helps, if many hams asking for crystals.

** When very near the oscillation point

On a 455kHz regenerative detector i measured a bandwidth of 50Hz/-6dB. Razor sharp, only the stop band attenation could be a little bit better.

Have fun,
Bernd DF3DL

Cuba is still on the State Department restricted list, so electronic
devices and parts are not allowed to be shipped there.

I sent Arnie 7.16 ceramic resonators taped to cardboard in a small
letter envelope and he DID get them.
Than later I sent transistors in a larger envelope.... but that package
never arrived ... and was not sent back to me.
Apparently something in this picture is against the rules.....

One of four things happened;

1. You sent it in a plain envelope First Class which would be put
through a sorting machines which would shred it.
2. It was suspicious as it was too thick, upon inspection it was
determined to be contraband and trashed, be grateful that charges were
not pursued.
3. It was intercepted by either Customs or Post Office people in Cuba
and kept as goodies to sell.
4. It's sitting in Cuban Customs and will eventually get there.

Take your choice and hope its reason #4

So WHY is transtransistors contraband to send to a professor to teach
electronics to newbies?

Because the State Department has placed Cuba on a Restricted Technology list, so shipping of electronics is prohibited.

Lest you forget Cuba has been for many years fomenting unrest in Latin America and the Caribbean, so they declared Cuba a Embargoed State that should not get electronic components. Burma, Afghanistan, Libya, Yemen, Iran, North Korea, Somalia, Yemen, and several other countries are on the list where sending electronic components are prohibited. About the only stuff allowed is food, and medicine.

Right or wrong it is the law and technically one commits a felony by disregarding the statues although they sometime ignore small quantities, but there is no guarantee that they will.

Thanks for the rules.
I had no idea Cuba was on the same sh**list as Iran and North Korea.

I have no childhood memory of the Cuban missle crisis and
I was 4 years old when President Kennedy was assassinated .
I remember that day like it happened yesterday.

I was sort of hoping things were changing:

http://www.t42us.com
http://www.t42us.com/team_antenna5088867_osm.jpg

ARNIE:
http://www.t42us.com/813.JPG

These are Americans in Cuba
3 of them are my neighbors.

Then just leave the crystals away, like i did with the "ECH81_v3.jpg". With this circuit i recognized, how strong cross talking can be within one tube. With or without crystal filter, there was no audible difference. After using two seperate ECH81, with a bw of 250Hz the cw-filter was almost too selective.

Standard crystals here are very cheap, one piece ~20 cent. Hope, in your country this begins to change now. If there is a electronic supplier, then maybe it helps, if many hams asking for crystals.

** When very near the oscillation point

On a 455kHz regenerative detector i measured a bandwidth of 50Hz/-6dB. Razor sharp, only the stop band attenation could be a little bit better.

Have fun,
Bernd DF3DL

Good luck finding 455 kHz crystals of good quality for 20 cents each.

If you know of a source at that price, we would be glad to know it!

FOR SALE: ANTENNAS

Slinky Dipole antenna system with center connector for standard PL259
plug on your coaxial feed line. Continuous inductance line, may be
adjusted in length to suit any HF band.

Excellent condition. Was used by a ham who became a silent key. He found
it very effective in the HF bands when used indoors across the ceiling.

Available for only $22.00 plus shipping. rthgrehgrt

26919. 716 regen uses only 2mA

Yahoo group: regenrx (2016 — 2017)
Date: 2016-08-13 17:17:38 UTC
From: Rob
Topic: 26919 Message: 26919

I got a phone call and ran away from the workbench without
unplugging the 9 volt battery from the 716 circuit.
More than 12 hours later I returned and discovered a CW contest blasting
away on the workbench.
To my dismay..... I thought I had erroneously killed off
....another... $5 duracell battery.....
but how could this still be running??????

I tested it in series with a digi ameter and it said 2 mA.

JUST 2mA?
I used to have an ICOM 706 that snarfed down 2 AMPs on receive... would
kill a fully charged car
battery in less than 8 hours.

I did not test any of the external amplifiers yet for amperage draw.
Mostly because I have not picked a permanent circuit yet to add to the
716 circuit.

Knightkit Spanmaster REGEN receiver 1958 from Allied Radio Co.

Nice piece of history here but also a usable receiver!
Restored mostly. It works., Has a new AC power cord, and a new front panel nicely constructed.
Otherwise original. Speaker cone has a tear but it works. I am sure this has an interestingstory.
Needs a cabinet but works as-is. From an estate here in Florida.

Available for $35.00 plus shipping.

Pictures on request via e-mail please.

26923. OT a little breadboard material question

Yahoo group: regenrx (2016 — 2017)
Date: 2016-08-18 01:54:07 UTC
From: William Wood
Topic: 26923 Message: 26923

Greetings and Salutations
I just bought a big beautiful breadboard
brand name is ‘Marketplace’. 12” x 16” x 1”.
Looking to use this for an experimenter’s board
and before I give it the marine spar treatment
would like to take a stain out of it. Right in the
middle of the board there is a mold or some kind
of stain I would like to remove… Thought about
bleach, but too late tonight to play with it, so
thought I’d run it by you guys for a hint or two…
A Good Will special :)

Bill,

Scratch the offending spot with the pointy end of a sharp pocket knife to determine the depth of the stain. If it's shallow, power sand the whole board until the stain is gone. If it's deep, note its location and choose a component from your next electronic project whose size will mask the blemish.

Only you will know "what evil lurks in the" breadboard!

Regards,

Charles

26927. what is this simple circuit doing

Yahoo group: regenrx (2016 — 2017)
Date: 2016-08-19 07:31:03 UTC
From: Rob
Topic: 26927 Message: 26927

I bought an $18 laminator to do PCB toner transfers.... understanding that the temperature controls need to be hacked to raise up to toner melting temps.

I documented the circuit board in the new laminator here:
http://www.learnmorsecode.com/laminator/al9.html

I am very puzzled how this circuit actually works:
http://www.learnmorsecode.com/laminator/al9circuit.jpg

There are two thermal snap switches that are normally on and they turn off when they reach their
snap temperature at 248 F and 293 F.
That sort of makes sense but not.....
because the two snap switches are in parallel.
So when the heat comes up to 248 degrees and one snaps off then the other is still on until it hits 293 degrees. I don't get it. WHY have the 248 degree snap switch at all.

There are two separate LED circuits made of a 1N4007 then 18K then LED connected directly to AC mains power.

I am a little confused about the green light circuit.
I am not aware of any other sensors or switches hidden in the heaters.
The heaters are 69 ohms when cold so with so little resistoance when cold I don't see why
power doesn't make it to that green LED ALL the time.

So if it gets turned on it looks to me like current flows through the heaters and into the green LED...regardless of the state of the snap switches.
BUT
the green light is supposed to indicate that the temperature IS high enough to laminate... so I think I am missing what triggers a "hot enough" state of that green LED.

This is a total teardown at this time.
Wires are cut. Thermostat switches are removed.
Thermal fuse is removed.
Motor is removed.

It COULD all go back together but I have no intention of using the 420 F thermal line fuse or the 293 F snap switch.
The goal is to hump out into 340 degree land and possibly 390 because brother toner melts at a higher temperature.

I just want to understand the circuit first before adding a PIC16F628 and thermister feedback control.

26928. Re: what is this simple circuit doing

Yahoo group: regenrx (2016 — 2017)

From: Brad Fayette
Topic: 26927 Message: 26928

When the 2 switches are closed, the green LED will be off. This is because current will take the path of least resistance, which is through the closed switches. When they are both open it will turn on. As for having 2 switches, it all depends upon mechanical placement. I would say that there must be 2 spots in this device which have to be at a minimum temp in order for it to work right. HTH.

Hi Tom,

Please excuse the intrussion only something you recently wrote peaked my interest. I read a recent posting of yours on the Yahoo regenrx group in which you wrote the following...

Tom wrote:
I've exploited that symmetry to use the standard feedback trick to linearize them when used as voltage-controlled attenuators, and I've never had to trim the feedback resistor more than an amount roughly equal to the resistor tolerances.
*** End quote ***

From the above would I be correct in thinking that you apply feedback in order to "smooth out" the control range of the JFET when used as a varable resistor/attenuator element to avoid the abrupt change from high resistance to fully saturated?

I would be very interested if you could supply a rough schematic or point me in the right direction for a practical example of such a circuit. While I have seen a number of attenuators using JFETs I have (so far) not seen a practical example of one using feedback to linearize the change in attenuation with respect to control bias.

Many texts describe the use of JFETs as possible variable attenuator elements but fail to provide enough practical information to use them as anything more than a switch in some cases due to the lack of control feedback.

Thanks for reading this and I look froward to heraing from you.

While I have never seen this particular device, In my misspent youth as an appliance repairman, I have seen many heating devices with two thermal switches. IN ALL INSTANCES THAT SECOND SWITCH (usually a fuseable link, a second higher temperature "snap"switch or a tilt switch) WAS A SAFETY DEVICE INTENDED TO SHUT DOWN THE APPLIANCE IF THE FIRST ONE FAILED!.
The use of a "safety" switch was mandated by fedgov In the 50's when it was noticed that a rash of home fires were caused by a certain GE appliance being left on and Murphy's 23 law of thermodynamics came into play (the temperature control switch failed).
In your case the 420 deg. link is the safety switch. I understand that you think that the PIC temp controller is safe, and it probably is, but please if you value your safety don't leave it out. REMEMBER MURPHYS FIRST LAW OF ENGINEERING (or tinkering) : EVENTUALLY, IF ANYTHING CAN POSSIBLY GO WRONG ,,, IT WILL!

I got a lot of responses really fast,
THANK YOU EVERYBODY

This makes sense to me.

So moving forward.....
The 420 thermal fuse needs to be raplaced......
something a little higher than the target toner heat temperature.
Found them on EBAY for all sorts of tempratures not far above 420.
So I'll get a few and start with the 420 and if the 420 pops after doing
the toner temp mod I'll move up a little until I fund one that doesn't pop.

Move to come.... this is a fun one.

26932. PCB laminator thermal sensors and fuses rebuilds parts

Yahoo group: regenrx (2016 — 2017)
Date: 2016-08-20 04:26:08 UTC
From: Rob
Topic: 26932 Message: 26932

There are two kinds of heat control method circuits in the laminators.
Method one is a comparator circuit that looks at a thermistor for resistance and the
easiest to hack.. by simply adding resistance to the thermistor feed line..... the comparator still thinks its cool so keep the heaters on a wee bit longer.

Method two is a thermal snap switch....pretty much just like a circuit breaker..... that pops off when the
temperature reaches a specific desired point.
This hack requires ripping out the existing thermal snap switch and replacing it with a higher temperature...then maybe needing to replace the thermal fuse also:

Both methods also employ a one time thermal fuse that will shut it all off for good if it reaches
melt down temperatures.
My laminators both had 420 F limit thermal fuses.
So I took a run down EBAY lane and found that you can buy thermal fuses for 13 cents....
so I ordered a kit of assorted values.
Noting that what ever heat appliance project we get to play with.....
there may be the need
to remove and replace this safety device.... perhaps with the next value higher than the
"method two thermal snap switch" mentioned above.

EBAY:
100pcs SF113E to SF240E SEFUSE Cutoffs NEC Thermal Fuse 10A 250V Assortment Kit

total with shipping $13.21. Just amazing. 13 cents

10 x SF113E 113°C 235 F
10 x SF119E 121°C 250 F
10 x SF129E 133°C 271 F
10 x SF139E 142°C 288 F
10 x SF152E 157°C 315 F
10 x SF169E 172°C 342 F
10 x SF188E 192°C 378 F
10 x SF214E 216°C 421 F
10 x SF226E 227°C 441 F
10 x SF240E 240°C 464 F
++

Finding the correct thermal snap switch may require some experimenting based on the toner
your laser printer uses.

I found multiple toner transfer articles on the web saying you need 170c-338F to melt and transfer
the toner BUT then more advice saying BROTHER toner melts at even higher at 370F.
Noting that the standard plastic pouch melting lamanitor using the thermal snap switch
is 145c -- 293 F so that explains why it takes 20 passes through a standard laminator to get
the toner to stick to the copper... if it ever sticks at all.... its just not hot enough.

I could not find a 190c but I did find a 200c thermal snap switch on EBAY.

HOTTER may not always mean BETTER to us.
If its too hot then the copper may delaminate off the PCB so lower is batter.

Toner get sticker and transfers to copper but tone CAN liquify at just a little hotter than
sticky temperature and then the roller pressure may squirt the liguid toner.

So then this raises the question of WILL 200c ...392 work with the BROTHER toner... or is that too hot?

More experiments coming.

170 c 338 F thermal snap switches cost ONE dollar:

EBAY:
10pcs-Temperature-Switch-Thermostat-KSD301-KSD302-170-C-NC

200 c === 392 F for $1

EBAY:
10pcs NO 5°C ~ NC 200°C 12 Values Temperature Switch Thermostat KSD301 (KSD302)

++

And then there is the motor speed hack.

Perhaps the temperature is perfect..... then comes HOW many times do you need to
pass the PCB through the rollers to get the desired toner transfer?

Some of the web hacks say you can build a fancy motor controller....
PIC16F84 stuff.....
and pulse the roller to move snail slow.... 1/2 a second motor on time then 10 seconds motor
off time to get the perfect one pass toner transfer.

The motors in my two laminators are 6 rpm and 4 rpm.
BUT
I broke the 6 RPM motor then ordered two on EBAY... and just for
fun...one of them is 3 RPM.
So when that shows up then perhaps an experiment with just plain
replacing the 6 with a 3 may make
it slow enough for a one pass toner transfer.
Noting that these motors cost just $5.

Soooooo.... I will document what works here when all the peices show up.
If the replacement of the 145c thermal switch with a 170c thermal switch
is enough to get good toner tranfers with the new $18 laminator then
that means we all can easily do this for under $20.

From: Jim Pruitt
Topic: 26932 Message: 26933

I would like to find d some thermal fuses but the highest I have found is 240 degrees and if running 370 degrees then a 240 might not work well. Yes I know you would leave it out but I like to play it safe. Did you have an auction number for the thermal fuse assortment?

Do you have links to info on what is needed (code) for the 16F84 and 16F628?

You mention multiple passes. Take a look at the Jameco kit to modify the Alps AL13P for single pass. I got the kit but refuse to pay over $200 for the laminator. There is an AL13 cheap but it is not industrial and don't think it is even close to the 13P.

I still like the DJ Delorie laminstir controller but have not found hardware for programming the Renaissance R8C-28 that he uses.

Thank you.

Jim

Hi Tom,

Please excuse the intrussion only something you recently wrote in peaked my interest. I read a recent posting of yours (message #26857 on the Yahoo regenrx group) in which you wrote the following...

Tom wrote:
I've exploited that symmetry to use the standard feedback trick to linearize them when used as voltage-controlled attenuators, and I've never had to trim the feedback resistor more than an amount roughly equal to the resistor tolerances.
*** End quote ***

From the above would I be correct in thinking that you apply feedback in order to "smooth out" the control range of the JFET when used as a varable resistor/attenuator element to avoid the abrupt change from high resistance to fully saturated?

I would be very interested if you could supply a rough schematic or point me in the right direction for a practical example of such a circuit. While I have seen a number of attenuators using JFETs I have (so far) not seen a practical example of one using feedback to linearize the change in attenuation with respect to control bias.

Many texts describe the use of JFETs as possible variable attenuator elements but fail to provide enough practical information to use them as anything more than a switch in some cases due to the lack of control feedback.

Thanks for reading this and I look froward to hearing from you.

26937. Artone Jr. #1

Yahoo group: regenrx (2016 — 2017)
Date: 2016-08-21 21:01:39 UTC
From: deadgoose@...
Topic: 26937 Message: 26937

Rummaging through the photos in this group, I came across three showing the "Artone Jr. #1" receiver, using a 1D8GT. This is the radio that I got me started in the hobby. However, the one I had, IIRC, had a paper template that was cemented to the plywood base to show the location of the various parts.

I got a set of plug in coils, and morphed it into a short wave radio. I also built an audio amplifier with a #30 tube, circuit for "Boy's First Book of Radio" by Alfred P. Morgan, so that I could drive a small loud speaker.

Anybody on the group ever build this radio, or know more about it? The interesting feature is using the grid leak R/C in the bottom of the coil, as the triode part (with the grid cap) is connected directly to the "hot" side of the tank coil and tuning capacitor. Mine also must have been made from surplus parts, as the tuning capacitor was a dual unit from a superhet receiver with the LO section removed.

IIRC, I got mine about 1949 or 1950.

Hello Rob

This is the circuit, i have built, similar ones can be found there:
https://groups.yahoo.com/neo/groups/regenrx/files/Exchange/Rx_40m_AGC.gif
https://groups.yahoo.com/neo/groups/regenrx/files/Exchange/Rx_40m_AGC.gif

To get enough dynamic range, two stages are neccessary. That might either be two audio amps or, like in my case, one if stage and one audio stage. The amplification can be regulated from ~1...100. This kind of circuit should work behind of a regenerative detector as well.

Typically an agc has an short attack and a slow release time. The attack time is a compromise, if the attack time is too fast, then without noise blanker sparks can make any reception impossible.

Best regards,
Bernd

Topic: 26937 Message: 26939

I have been for the last week sorting my books and manuals, sorting some with like subject, some to sell, some to try to donate. (Finding a site that will scan and host online

is not so easy.) I had been keeping equipment manuals in one place, but i decided to try to keep them with the equipment so far as possible. I have seen so many estate sales

where the manuals just disappeared. So i found this booklet for the “Electro-Kit No. 1” by “Keane Associates”. This must be the same radio kit, as it uses the 1D8 valve and

does have a paper template.

The circuit is an odd one and i had to redraw it to my satisfaction, to understand it.

The top of the coil and the top of the tuning cap connect to triode grid.

The bottom of the tuning cap is grounded. The tube filament is grounded.

The bottom of the coil goes thru a 500 pF to ground.

So the 500pF and the tuning cap are in series across the coil. Their connection point together is ground.

The triode plate goes thru a 500pF cap to the bottom of the coil (which is 500pF above ground.)

So you have a Colpitts oscillator.
(gridleak R is from bottom of coil to ground (in parallel with the 500pF cap.)

So the thing is always in oscillating state. That’s odd and altho i have never tried to use the thing, i think it would be unusable for music listening, since you have to be

absolutely right on zero beat or the music sounds “off”. Tuning is direct drive of the cap, no vernier action.

Another odd thing is that as the variable tuning cap tunes thru its range, the feedback ratio in the tuned circuit has to change, from approx 1: 1.5 to 1: 20. Apparently

it still maintains oscillation over that range.
The booklet does say that if you have strong local stations to listen to, you can disconnect the feedback feed cap from triode plate (to the top of the other 500pF

cap.) Then it’s a straight grid leak detector circuit.

Clear as mud?

Another oddity is that the schematic lists tubes 1D8 or 3A8, but it doesn’t tell how to wire the filament pins for 1.5 volt operation of the 3A8.

Re the two-gang tuning cap with one section missing: i’m sure the kit company bought them this way. I’m sure i have seen the same thing used in some other kit,

maybe a Boy Scout radio kit.

Paul’s idea of adding a #30 audio stage is pretty neat. And also using shortwave coils – but i think you’d probably have to keep one hand glued to the tuning knob

to keep anything tuned in!

Mike, thanks for clearing that up! I didn’t know about the Artone Jr. Using two 1T4 is the hard way to do it, and had to cost more.

The easier tuning on the strong locals – is that due to the pulling effect, locked oscillator effect?

-H

☐

Paul, You were probably looking at photos that I posted. There are two radios shown there. The one with the 1D8GT was sold as the Electrokit #1. It was also my first tube-radio that I built at Cub Scout age. This radio is somewhat unique among regens in that it uses the Colpitts circuit rather than the usual Armstrong or Hartley. Also, it has no regeneration control. You have to tune it to zero-beat on AM stations - easily done on strong locals, but very tricky on weak or distant ones. The schematic shown is for the Artone Jr. which uses two 1T4 tubes instead of the two sections of the 1D8GT. The circuits of both radios are the same and they were sold in the same size box with the same pictures on the box cover. Either one could be bought with the two-gang surplus tuning cap. or a conventional 1-gang tuning cap. shown on the cover and that did not necessisarily indicate what was actually in the box. Mike, W6MAB

From: Hubert Miller
Topic: 26937 Message: 26944

That’s why i was thinking the tuning was easier to tune in locals than distant weaker stations: the strong stations (might) tend to pull the oscillating detector and tending to lock

it to the carrier.
I kind of don’t understand the company’s logic in having it oscillate all the time. I suppose it made it a tiny bit easier to learn, as you wouldn’t have to learn how to peak a

regen control.
Do you remember on local stations it being stable enough to reasonably listen to music?

-H

>Hugh, I don't know much about "pulling effect". What I can tell you is that the Electrokit #1 had a serious hand capacity problem. This didn't show up on strong locals, but after tuning for zero-beat on weak or distant stations, you couldn't let go of the tuning knob without the set going back into oscillation. At the time we lived in northern New Jersey, and I could tune in all the New York City stations and listen for hours with no problem. However after tuning in, for example; WSM Nashville, WCCO Minneapolis, or XERA a Texas border station, I didn't dare move a muscle, let alone release my grip on the tuning knob, or the set would start squealing again. IIRC, mine was easy to tune. I believe the antenna coil had a powdered iron core. No feedback, I think. I assumed it was an "infinite Z" detector, just depending on the grid-cathode rectification, and amplified by the triode itself. Later, I found out about grid lead detectors, and built some of those.

Slightly OT, but there is an interesting superhet in "Radio for the Millions," using a 1A7 and a 1D8GT.

Thanks for the answers!

If anybody comes up with more information, I'd appreciate it.

As far as I know, it is a thermal fuse. As used in a heating appliance. If not in a heating appliance, just substitute with a slow blow of the anticipated voltage and current listed on your device.

YES YES YES its a thermal fuse..... readily available 13 cent thermal fuse.

but NO
the question is what are the crimp connectors called when you try to buy them....

AND THE ANSWER IS:
high temperature crimp (or butt) connector

used in heating appliances to HOLD the THERMAL FUSE leads together with feed wires because
the wires get hot enough to melt solder.

AND
the wires and crimps and fuse gets covered with a fiberglass fireproof sleave.

26951. toner laminator melted nylon gear

Yahoo group: regenrx (2016 — 2017)
Date: 2016-08-24 08:25:09 UTC
From: Rob
Topic: 26951 Message: 26951

PCB toner transfer taget temperature was 340 degrees.
Pictures of the experiment here:
http://www.learnmorsecode.com/laminator/index.html

Two power switches ... one for the motor and one for the heater
control circuit.

Original laminator temp topped out at 280 degrees Fahrenheit.

Temperature increase to 370 degrees was achieved by adding
a 1K resistor inline with the thermistor... but it kept climbing
to 380 degrees so I terminated the heater power supply line.

Playing with resistors

http://www.learnmorsecode.com/laminator/royalmods4.jpg

found that 22 ohms made 320 degrees Fahrenheit

http://www.learnmorsecode.com/laminator/royalmods6.jpg

and 51 ohms made 354 degrees so that was pretty much a declaration of
circuit wizard victory
when the temperature stopped climbing and hovered between 348 and 355
degrees.
So I grabbed a circuit board and a toner transfer image and fed it into
the hot slot but it did not grab the board at all.....
http://www.learnmorsecode.com/laminator/royalmods7.jpg
because the rollers stopped spinning:
http://www.learnmorsecode.com/laminator/royalmods9.jpg

well... .. like I said... no surprise there.

The end of the roller where the metal axles protrude ..... the metal
was 300 degrees.

Does anyone have a source for these gears made out of metal?

What pre amplifier am I missing for the 716 regen project?

The receiver circuit works fine.... when I plug it into a store bought
HONEYTONE guitar
amplifer
http://www.learnmorsecode.com/716/etch/0703.jpg

BUT
most other ampifiers make headphone audio... barely desk top audio:

http://www.learnmorsecode.com/716/lm386.html
http://www.learnmorsecode.com/amp/tl431PCBdone1.jpg
http://www.learnmorsecode.com/amp/tl431VU2PPP09.jpg
http://www.learnmorsecode.com/amp/tl431.html
It took weeks to get barely a peep out of the TDA7052 IC
and I got whisper quiet CW out of a TDA2030

Latest experiment was
http://www.learnmorsecode.com/amp/SM7UCZamp2.jpg
http://www.learnmorsecode.com/laminator/hotcakes9b.jpg
which is dead silent.

ALL of these experimental amplifiers come to life when I
plug them into a signal generator or an IPOD music player.

So what am I missing here.....
that the HONEYTONE guitar amplifier has in it?

http://www.learnmorsecode.com/amp/honeyrule.jpg
The TWO TL072 pre-amp circuits?

Topic: 26954 Message: 26955

A guitar amplifier has higher gain than a line-level amplifier. CW from a receiver may be very low so you may need more gain than you can get from some amplifiers. Try adding 20dB (10x voltage) of gain at the end of the receiver.

Can you recommend the circuit to add that does 20dB (10x voltage) of
gain at the end of the receiver?

I'd personally recommend a TL071 wired for Av = 10. Use a capacitor around the feedback resistor to lower the gain at high frequencies. If you're trying to find amateur radio signals only, make the roll off around 2.5 KHz. The signal level will still be high enough at 3 KHz that you won't notice much reduction.

You could also make a one-transistor gain stage. It's easy enough to make one with a gain around 10. 2N3904 or equivalent should be enough. You'd get more predictable results with the op-amp unless you're dedicated to a discrete component design.

I don't know what the circuit of the regen you're building looks like but it sounds like low gain is your problem. Are you having to turn the gain of the honeytone amplifier up high?

All those pictures..... and I missed putting the circuit at the top of
the question.
Sorry about that.....
schmatic here:
http://www.learnmorsecode.com/716/VK3YEmodKB3BYTv2.jpg
details here:
http://www.learnmorsecode.com/716/716.html

PCB here
http://www.learnmorsecode.com/716/etch/index.html

I am not opposoed to op-amps as much as I was hoping to use discrete
components
as much as possible.

Yes.... I had to turn the honeytone gain way up high.

Look at rod elliott's audio Web site for circuits. He has on there circuits
that will suit you...and they're discrete components.

Could you be just a little more specific?

rod elliott google out to tons of web pages.

I landed on a hundred circuits here:
http://sound.westhost.com/projects-0.htm#pre

What did you have in mind from Rod Elliott?
Have you built any of his circuits?

Read this. The two transistor feedback pair should be what you're looking
for.

From: Rob
Topic: 26954 Message: 26962

thank you
Very nice details..... will take a while to read it all.

Of course supply voltage says +18 volts

I was hoping to figure out a 9 volt battery solution.

Make sure the audio amplifier has a high impedance so that it does not
load down the signal.
10,000 ohms times 20 = 200,000 ohms. Or maybe make the first audio stage
a follower circuit.

Most of those will work with 9v. The point is that the signals you are amplifying are less than a millivolt, so the useful output range of these amplifiers is much higher than what the output would be amplifying a higher voltage.

HOW do I
Make sure the audio amplifier has a high impedance so that it does not
load down the signal.
WITH WHAT CIRCUIT?

From: J Ed
Topic: 26954 Message: 26966

The circuit isn't as important to a high input impedance as is the values
in the circuit.

Simple: use a JFET (MPF102, J201, or similar) to serve as a buffer to the
preamp. Use a 1M resistor from the gate to ground. Figure out what biases
the current in the FET between IDSS and pinch-off, then bias it roughly
halfway. Use a drain resistor that drops about 1/2 VCC at the current. Use
that to feed the input of your preamp.

That'll work. A J201 will have higher gain. You'll need to tweak the resistor values because they have less current than MPF102. Since the signals you will see are very small, you could replace the series 5.1v diodes (which would clip signals higher than 5.7v) with parallel 1N914 diodes (or similar). When I say parallel, that means one with the cathode to ground and one with the anode to ground. This will remove high-amplitude noise pulses that will otherwise overload the amplifier and probably hurt your ears.

Topic: 26954 Message: 26969

thank you

I recall that the purpose of the 5.1 zeners was strictly as a protection
from static electricity.
I think the circuit was designed as a microphone or electric guitar pre-amp
which carries a zillian volts static jolt every time you plug your
guitar into it.
So it makes sense to do the 1N914 clipping filter.

I was also considering this dual mpf102 pre-amp:
http://www.learnmorsecode.com/amp/mpf102B1.gif

26970. Re: [regenrx] what pre amplifier am I missing for the 716 regen project

Yahoo group: regenrx (2016 — 2017)
Date: 2016-08-30 06:28:21 UTC
From: J Ed
Topic: 26954 Message: 26970

My experience has taught me two things about the MPF102...

- They have low gain at 9-12v, for audio amplifiers. I find they are more useful for RF.

- Simulation models of them are useless. The ones that are floating around there are not helpful in predicting JFET performance.

So here is what I did. I had a large bag of MPF102s sitting in my parts bin. I took 15 of them and ran a test, where I grounded the gate, hooked the drain to 12v, and placed the source to ground through a series of resistors.

The first one was 1 ohm, which allowed me to find IDSS, which is the max current the drain will conduct with 0v between the gate and source. Then I used a 100k ohm resistor to find the pinch off voltage. This is the voltage from gate to source where negligible current flows. Then I chose three resistors in the range that would give me good midpoint values. With that data, I could make a curve that showed a rough estimation of how the FET would work.

Use J201s or similar for audio gain. Look at www.runoffgroove.com. They use JFETs, mainly the J201, to make guitar booster and effects that simulate tube amps. You could find a good deal of help there. I'd recommend a 40 dB preamp with a gain control so you'd have more gain than needed.

The diodes 1N914 or 1N4148 will do roughly the same thing as the zener for large signals. For small ones, they will be almost transparent. Almost. If you put two series diodes in the circuit, you could get improved distortion when receiving multiple signals.

Ed AE7TE

26971. 716 regen project, et al audio amplification

Yahoo group: regenrx (2016 — 2017)
Date: 2016-08-30 11:14:20 UTC
From: kf8zn@...
Topic: 26954 Message: 26971

Rob,

How many ways do you intend to skin this cat?

I showed you how to get 74db gain from an LM386, which you stated had worked.

http://www.intio.or.jp/jf10zl/LM386.htm http://www.intio.or.jp/jf10zl/LM386.htm

http://www.intio.or.jp/jf10zl/LM386.htm

http://www.intio.or.jp/jf10zl/LM386.htm http://www.intio.or.jp/jf10zl/LM386.htm 7.How to get 74dB by LM386 lm386.gif LM386 is very popular IC also in Japan. It is used in Radio receiver. The power of it (500mW) is enough for the personal use...

This darlington circuit works well also, offering VERY high input impedance, and GOBS of gain.

26972. Re: [regenrx] 716 regen project, et al audio amplification and cat skinnings

Yahoo group: regenrx (2016 — 2017)
Date: 2016-08-30 14:54:22 UTC
From: Rob
Topic: 26954 Message: 26972

I did not get room filling audio with the JF10ZL LM386 circuit.
I got just barely enough headphone level audio out of a 3 inch 8 ohm
speaker.

The goal here is to find a good audio output circuit to mate with the
716 regen project circuit
that can be repeatable cheap with the newbies, kids and scouts.

Preferably discrete components but I am game for anything....
considering that a TDA2030 kit now costs $1.69 from
EBAY. Noting that TDA2030 could be used with a kids regen project and a
kid could also play an electric guitar through that TDA2030 kit I
doubt it would ever be tossed in the trash.

The internet is chock full of examples using transistors and various ICs
like TL741 and MPF102 and all levels of TDA2030 etc...

I wanted to compare the results of actually building these circuits and
then in the future be able to pick an amplifier
any time to add to radio experiment circuits. I had in the past used
LM386 with very mixed results.

BUT
the 716 regen circuit does not play well with these amplifiers for
me..... so it raised the question of
what to add in between 716 and the amplifier circuit.... and the issue
of how to make the audio amplifier
circuit have a high impedance so that it does not load down the signal
has become the current
design phase.

I had not played with darlington pre-amps yet.
Is that some radio designer high impedance secret I need to learn?

26974. Crystals

Yahoo group: regenrx (2016 — 2017)
Date: 2016-08-31 20:06:02 UTC
From: Leonard Meek
Topic: 26974 Message: 26974

I think I've been pretty naive about crystals. I've had trouble getting my R'dynes to work dependably, and it seems to be the fault of my crystals. I have a couple hundred, mostly HC-6 and FT-243. I've always believed the marked frequency as gosphel, but while diddling with my Mk.26 I noticed some inconsistancies. Crystals marked with the same frequency behaved differentl, so I threw together a little crystal tester. Many of the crystals I was using were nowhere near the freq stamped on the case. I checked them against the pattern on my scope to verify the results. Most were within a couple of Hz, but some were way less, and others were totally dead. Someone posted a blurb here a while back on checking crystals, but I don't remember who. I don't understand all I know so I need a tutorial on crystals. I'm going to have to test them all before I mess with my R'dynes any more.

Hi Leonard,

I tested my crystals with my Knight T-60 transmitter and dummy load with a frequency counter loose coupled to the dummy load. Some of them - as you have said - are close enough for amateur work and some are far, far off. A few are dead. The Knight T-60 is not required. Any old mopa style TX with or without a couple of extra stages will do the job. A frequency counter isn't needed either. A receiver that can tune the crystal's frequency is just as good. If the crystal is far off the receiver might be clumsy to use. If it's dead there will no power output - not even a little. My old transmitters all use the FT-243 but adapters are easy enough to build for testing other form factors. Those old TXs will sing way outside of the ham bands if you plug in out-of-band xtals. At least mine will. The bandswitch might say 40 meters but the transmitter doesn't really *know*.

73,

Bill KU8H

Thanks, Bill. I don't have a xmtr I can use for testing. I built a little Colpitts oscillator that worked quite well with my counter for crystals <10MHz. I can also make a rough estimate with my scope by taking the reciprocal of the time between positive peaks. It's time consuming and not as accurate as the counter, but at least I'll know which ballpark I'm in.

Leonard

From: Tom Lee
Topic: 26974 Message: 26977

I would be very surprised to hear that the HC6-packaged crystals were grossly out of tolerance, unless they started off that way or were physically damaged (including a loss of seal). But vintage FT243-packaged crystals were/are unstable because etching to passivate the surfaces had not yet been implemented or mastered. The usual symptom is an increase in frequency, accompanied by a decrease in activity, over time. Eventually many of these units simply stop oscillating altogether. These can be revived with a little etching (or even a pencil mark in the right place), but getting them back on frequency, and keeping them there, is not trivial.

Another failure mode was simple corrosion of the metal electrodes pressed against the crystal's faces. If your crystals have been stored in a damp environment, that can be a problem, particularly with early production units that used brass.

The "Chi-Com" (Sinometer VC2000) I bought a couple years ago has an Xtal check function that I found to be very handy. Not sure of the circuit used (other than that it's solid state ;-) but you plug the xtal in (if it has leads or if the Xtal doesn't, I have a pair of very short leads with small gator clips I use.

I found that 'overtone' xtals measure the fundamental. Hey, it's not optimized for some of the old transmitting xtals (think it's more for modern ones), but it gets you in the ballpark, especially if you don't know anything about the xtal to begin with..

I think I accumulated these crystals when I was in the Navy back in the '50's. They were definitely in a wet environment. Out of nearly 100 FT-243 crystals, about a dozen were anywhere near the freq stamped on the case. The rest were all somewhere between 4 to 6 MHz, even though they were marked 13 to 17 MHz. I found 1 good one at 15 MHz, which made my Mk.26 start working like it should.

Another thing that puzzles me, why does the crystal produce a ragged waveform? Is that normal or is something wrong with my setup?

26981. Re: [regenrx] Crystals

Yahoo group: regenrx (2016 — 2017)
Date: 2016-09-01 05:11:23 UTC
From: Tom Lee
Topic: 26974 Message: 26981

It is definitely not normal -- the high Q of a crystal should lead to a near-perfect sinusoid. However, not all oscillators are designed to set the amplitude by some graceful mechanism, so anything goes. Also, if there is enough gain at both the fundamental and overtone modes, it is possible to oscillate simultaneously at more than one frequency. The overtones are not at exact integer multiples of the fundamental, so you can get odd waveforms as the harmonics of the fundamental beat against the overtones.

Very interesting. It is quite possible that those were early 3rd
overtone crystals, with poor activity at the overtone, or the oscillator
simply had too much gain at the fundamental, so that won out over the
overtone.

Thanks for the data, Leonard!

Hello Leonard,

I built a Colpitts oscillator using bipolar transistors.
When I took the signal from the cathode (sorry, I meant emitter) I got a distorted waveform.

I put a capacitor in series with the crystal and took the signal out from the junction of the crystal and the capacitor. There, I got a sine-like signal.

Later I read that the signal taken from the cathode (sorry, source) of a JFET oscillator was distorted because the device was biased to operate as a class "C" device. From my understanding this means that the bias is set so that current flows through the amplifier for about 1/3 of the signal cycle.

A long time ago I built a 500kHz oscillator (based on a 'toob', and yes, it had a cathode, not an emitter).
I was surprised to see that the signal was rather square wave-like but with a slow-rising and falling edge.
That meant the 'toob' had too much gain, so it was both saturating and cut off during the cycle.

More than that, I saw the 7th harmonic on the 'high' edge of the signal - I could easily count the seven "cycles" in the overtone. (I thought that was 'way cool' and took a photo of the signal! It was very exciting so "see" evidence of what I had only read about in books!)

So - I hope my account here about distortion helps the general understanding about what's going on in your circuit.

One final point. The 74HC4060 is a very handy chip to have where crystals are concerned. (Or even a vanilla HEF4060) With a power supply, the chip and a crystal you can quickly build a 'knock-up' oscillator. An additional bonus is that the chip will provide signals that are binary divisions of your crystal frequency. The chip costs less than $1.00

Les, I've noticed the effect you're talking about. One problem I have is my counter doesn't seem to be very sensative, or maybe it's trying to respond to all the overtones. But using my scope and a calculator I can quickly separate the crystals into "close" and "far out" catagories. This gives me more predictable results with my R'dynes, but since my dials only have logging scales, I still need to make up tuning logs for each coil-crystal combination.

Hello Leonard,

Does your counter have a control called "trigger level" or "level" or something like that? If "yes" then feed the signal from a crystal that shows some harmonic frequency and adjust the "level" and watch the counter/frequency. You may be surprised.

As for logging scales, I think these are pretty useful for us novices, especially if we have a 25 (or 50) kilo-Hertz "spot" marker. I built a "way cool" circuit that generated 1,000kHz, 500kHz, 100kHz and 25kHz "spots". I call it my "leopard" circuit, because the spots don't change!

And while I'm here - how many readers use a 'spot' maker, and how many would be interested in a card (or circuit) that did this simple task?

Keep up the good work, Leonard.
I like your designs (and circuits).
If you knew how many hours I have spent looking at each circuit diagram you'd be pleased!

Hi Gangue,

I have a 'spot maker' or two or three here. Between/among spot makers, rf signal generators, frequency counters, calibrated receivers, and such we can identify some number of "spots" on the logging scale. Then put those "spots" into a spread sheet so that it can generate and print a 'tuning curve' with logging dial numbers on one axis and frequency on the other (no z-axis needed). Give this a try with your "pretty" dial that reads directly in frequency and see that it is really curved and not perfectly straight across it's tuning range. All that money for perfection. Shame!

The RAK-7 and SW-3 have logging scale dials and both of them are slightly curved through most of the tuning range with a little more curve at each end. My "pretty" dials like the ones on the Kenwood VFOs and the Heath rigs also have that curve. They don't use quite the entire tuning range of the tuning cap so the dial scales are a little straighter (avoiding the decreasing radius at the ends). Other tricks can decrease the error rate as we tune across the range too. Logging scales are far, far from "useless". I have been able to preset radios with the old zero to 100 (or 1000) logging scale dials to an expected net frequency and end up zero beat with the transmitter when it comes on air. That's not any worse than other receivers with fancier scales.

OT, after a 7 year hiatus I'm getting ready to put my 10M beacon back on the air (why do I always do this during the sunspot lows). I was looking for an IDer kit and ran across this little amplifier. It's cheap and simple, but may fill the need for somebody.

NO, I'm not in the market or need one. But there has been a lot of discussion on this list about various versions.

Heh,

Why would you need a beacon when the cycle is high and everybody knows
the band is open to everywhere all the time - almost. When conditions
get spotty is when a beacon is really needed.

716 regen with darlington pre-amp works fine with all amplifiers.

Working through the stack of amplifiers tried with little great results
I added this 2N6486 darlington pre-amp
http://www.learnmorsecode.com/mpf102/darlington01.jpg
http://www.learnmorsecode.com/mpf102/index.html
and ALL of the experimental ampifier circuits cames to life with
desktop audio.....
... LM386... TL431... etc... came to life.... way cool.
And I've been listening to the MI contest tonight:
http://www.miqrp.org/contest.html

26998. Re: 716 regen with darlington pre-amp works fine with all amplifiers

Date: 2016-09-06 13:05:44 UTC
From: Rob
Topic: 26997 Message: 26999

I could tell no difference between using the storebought honeytone amp and
the cobbled circuits.
And the honeytone IS the benchmark comparison..... because I never know
if there IS
CW on the air to listen for on a new experimental circuit unless I
plugged in the honeytone first.

I have made that mistake. I finished contruction at 5AM and heard
nothing, thinking the pre-amp circuit
was a failure and then plugged in the honeytone and heard nothing on the
air, then
12 hours later the same configurations I heard non-stop CW contesting on
both.

As far as hiss goes.....
one of my audio tests is to plug an electric guitar type instrument... a
4 string electric mandolin....
into my audio circuits.... and play classical music:
http://www.jimthorpelivemusic.com/mando/02joyofmansdesire.mp3

This particular current experiment definitely did do precisely what is
what supposed to do
for pre-amplification and the music that came out of the amplifier
circuits was clean in most of the circuits.
One circuit needs some tweeking... the TL431/2N3904/6 push pull circuit
had a lot of grungy distortion...overdeviation clipping.... so I think
I would add some pots to dial in that circuit if I had to use that one.

I have one more issue to work out with the pre-amp with battery
isolation issues.

I shared one 9 volt battery with the 716 regen reveiver and the 2N6426
PCBs but when I
tacked an amplifier circuit to the pre-amp I got constant steady
oscillations.

This discussion is giving me clues as to why my 716 seems dodo.

In the loft I might have an old cassette-player. The cassette
record/play head produces a very low output, so the AF amp must be
high-gain and might do the trick.

Any thoughts?

Michael

I am not the first person to declare the audio is very low coming out of
the 716 circuit.
Thats why I banged away at amplification circuits for 3 months.
My first pass at the darlinton pre-amp was usinging 4 sets of input
resistor pairs with a jumper for selection.
I was looking for the solution to the question of which of the four sets
was the right set to use.
So peeling out the optional parts the final layout is much simpler:
http://www.learnmorsecode.com/mpf102/darlingONE2.jpg

I got desktop audio out of the one dollar LM386 kit through the pre-amp:

http://www.learnmorsecode.com/help/LM386amp.JPG

27002. Looking for the 716 regen initial message

Yahoo group: regenrx (2016 — 2017)
Date: 2016-09-09 16:22:22 UTC
From: slimjimwas@...
Topic: 27002 Message: 27002

I'm looking for the initial message for the 716 regen thread.

I automatically download all regenrx posts (from about 2004) to Eudora, my email client, and could not find it there. I tried going directly to Yahoo Groups, but no luck there, either. I decided it probably started elsewhere - maybe www.learnmorsecode.com http://www.learnmorsecode.com/716/index.html

http://www.learnmorsecode.com/716/index.html

www.learnmorsecode.com http://www.learnmorsecode.com/716/index.html Version 2 https://www.youtube.com/watch?v=iYap-hCLD7Y VK3YE REGEN using 7.16Mhz resonator: https://youtu.be/WREwJQVE8xI?t=390 based on F5LV...

Am I correct?
Jim

27003. Re: [regenrx] Looking for the 716 regen initial message

Yahoo group: regenrx (2016 — 2017)
Date: 2016-09-09 19:28:13 UTC
From: Rob
Topic: 27002 Message: 27003

someone posted a link to the YOUTUBE
VK3YE REGEN using 7.16Mhz resonator:
https://youtu.be/WREwJQVE8xI

and version TWO
https://www.youtube.com/watch?v=iYap-hCLD7Y

which I then chased down a schematic and began experimenting with this
7.16 resonator circuit
so I documented what worked for me:
http://www.learnmorsecode.com/716/index.html

http://www.learnmorsecode.com/716/716.html

and then chased down how to make it louder....
because I bare got headphone audio out of my first LM386 cicuit.....
but
unsuccessfully playing with TDA7052 chips
then definitely successful
with an array of amplifier circuits:
http://www.learnmorsecode.com/amp/tl431.html
and more recently the addition of a high impedance PRe-AMP
darlington circuit:

http://www.learnmorsecode.com/mpf102/darlington01.jpg
http://www.learnmorsecode.com/mpf102/index.html

Once I added the 2N6426 pre-amp circuit I got desk top or room
filling audio out of all the other circuits
experiments that were way too low audio before the addition of this pre-amp.

27004. DXERS UNLIMITED SCRIPT FOR SUNDAY 11 SEPT PROGRAM

Yahoo group: regenrx (2016 — 2017)
Date: 2016-09-10 15:12:22 UTC
From: Prof. Arnaldo Coro Antich
Topic: 27004 Message: 27004

Radio Havana Cuba
Dxers Unlimited weekend edition for Sunday 11 Sept 2016
By Arnie Coro
Radio amateur CO2KK
Hola amigos radioaficionados all around the world now enjoying like I am , the much better propagation conditions prevailing thanks to the proximity of the autumn equinox... Yes, as we approach the northern hemisphere autumn equinox, despite the fact that solar activity is low, nevertheless we are happy to see better conditions on all bands from 160 meters to 10 meters... I am Arnie Coro, radio amateur CO2KK your host here at the weekend edition of Dxers Unlimited, and now I will read part of a propagation report that says:
Compared to the last reporting week, the week from September 1 to 7 showed an average daily sunspot numbers that was down, but the solar flux increased, and geomagnetic indices were much more active.
Average daily sunspot number declined from 60.1 to 46.4, while average solar flux went from 87.9 to 95.1. Average planetary A index increased from 8 to 26.6, while average mid-latitude A index rose from 6.9 to 18.1.
The daily planetary A index on September 1-4 was 36, 39, 40 and 28.
It looks like an echo of the solar wind which caused this activity is expected on September 28 through October 1, when the predicted planetary A index is 35, 38, 40 and 25.
Predicted solar flux will be 92, 90, and 85 on September 11-13, 80 on September 14-16, 108 on September 17-19, then 110, 105 and 110 on September 20-22, 112 on September 23-24, 108 on September 25, 105 on September 26-27, 100 on September 28, 95 on September 29 through October 1, 98 on October 2-4, 95 on October 5-6, 90 on October 7-8, 95 on October 9, 100 on October 10-11, 105 on October 12, and 108 on October 13-16. After October 16 flux values meander from 105 to 112.
So , here is my advice, enjoy the favorable HF propagation conditions for the next four weeks ....
Item two: I wrote an article for the Cuban National Amateur Radio Federation web site titled ¨ Propagation Windows and how you can enjoy them ¨ It centered on a short term propagation forecast that showed high probabilities of nice nation wide good 40 meters band conditions from about 4 pm to 8 pm local time.... The article was read by many Cuban radio amateurs and it sparked a lot of activity during the afternoon hours during the past several days. Two of the popular 40 meters band SSB round tables received a substantial increase of check ins.... indicating that the propagation prediction was quite accurate. Now I will be giving the finishing touches to another article about DX windows that will be available from Cuba and the rest of the Caribbean during the equinoctial season....
Item three: 10 meters band operators, please pay attention to what follows.... the 10 meters band beacons will tell you about band openings

that go unnoticed because the lack of amateur radio activity ... In other words, the automatic beacons that are on the air 24 hours a day will tell you to start calling CQ DX even if the 10 meters band shows no stations on the air... The Trans Equatorial Propagation Season is now in full swing and this means that DX on 10 and 6 meters is possible.
Item four: Testing the new generation of LED lamps that are now made here in Cuba to replace the classic 20 or 18 Watts fluorescent lamps... The LED lamps use a switched mode power supply of the auto volt type to feed the five chains of LED lamps that are spaced uniformly along the length of the replacement lamp that fits into the same sockets as the fluorescent tubes... So far my measurements are very encouraging.... seems like very good engineering went into the design of the switched mode power supply that converts the AC line voltage from 85 to 250 volts into the 12 volts direct current used by the LED lamps. Each fluorescent lamp replaced by the new LED fixture saves about half of the electricity used by the classic lamp and produces more light output, plus the fact that the estimated lifetime of the LED assembly is many times longer than the fluorescent 20 or 18 Watts lamps... When installing the new LED lamps you simply remove the starter , and that's it, but if you wish you can also remove the ballast reactor too....
Stay tuned for more radio hobby related information coming from rainy La Habana , Cuba where a low pressure system moving very close North of us is producing much needed rain ...
Back in a few seconds amigos

short musical intercut

Si, sure, this is your favorite radio hobby program, the one and only providing coverage of the ninety two different ways you and I enjoy playing with our radios... Here is now more information about a recent scientific research paper that demostrated the world wide increase in radio frequency noise detected within the frequency range from one hundred kiloHertz to ten megaHertz... The authors compiled actual noise measurements made using time proven technologies and came to the conclusion that the AM medium wave broadcast band reception conditions all around the world have deteriorated significantly especially in urban areas, and even in rural areas the presence of so many electronic devices that use the switched mode power supplies have spoiled the reception of AM stations quite significantly. As a matter of fact, the authors of the well documented research simulated under laboratory conditions how the presence of broadband noise makes reception of even the most powerful local AM stations quite difficult. Another related study, shows that within the frequency range from 10 megaHertz to 100 megaHertz reception has also become more difficult in high density of population urban areas.... Low cost devices like cell phone battery chargers and similar gadgets are the culprits to blame for the ever increasing radio frequency broad band noise levels that are making reception of signals so difficult... Several recent field intensity measurements I made in my residential neighborhood show that TV sets, computers and the cell phone chargers seem to be the main contributors to the extraordinary high noise levels that the spectrum analyzer show

within the frequency range from 500 kiloHertz to one hundred and ten megaHertz.... Now let me add that turning off the AC power system by switching off all the circuit breakers that feed my home, showed only a very slight decrease in the noise levels, indicating that nearby homes are also an important source of the broadband noise that makes AM broadcast band and short wave reception so difficult .
Item five of the weekend edition of Dxers Unlimited... a recent announcement made by one of the world's radio receivers manufacturers seems to be the good news everyone has been waiting for... A new DRM capable receiver that has a multi mode decoder capable of AM, FM and DRM reception and that may be sold at a price equivalent to the present days portable high quality AM, FM and short wave receivers... This may be the breakthrough we are all waiting for, so that DRM and DRM plus and DRM 30 digital radio technologies can finally start to enter the worldwide market place. India seems to be the nation that is most advanced in the creation of a full coverage network of DRM high power transmitters, some of which are now on the air, although the number of radios that can pick up those programs is minimal to say the least.
Now amigos at the end of the show two remainders... we are still well into the thunderstorm season so please disconnect all your external antennas and AC power line cords when you finish listening or operating your ham radio stations... second reminder, it is always important to hear from you... so please take a little time and send me your comments about today's edition of Dxers Unlimited to inforhc at enet dot cu, again inforhc at enet dot cu or via air mail to Arnie Coro Radio Havana Cuba, Havana ,Cuba

27005. successful thermistor PIC POT experiment

All I can say is WOW.
I can't believe this was so easy.
And cheap.

thermistor cost is 20 cents.
PIC16F628 cost a dollar.

MOC3020 Optoisolators cost 30 cents
BTA20 traics cost 40 cents

Here's a challenge for your homebrewed Regen receiver.

Just yesterday, after a 7 year hiatus I 'reactivated' my 10 Meter beacon. Rig is a Realistic HTX-100 running ~20 Watts CW into a Cushcraft AR-10 'Ringo' antenna that's 14 feet AGL. Frequency is 28.290 MHz.

--

Specializing in DXing NDBs (Longwave Beacons)
Phil, KO6BB, http://www.qsl.net/ko6bb/
KO6BB/B beacon, ~20W to a Ringo Vertical on 28.290 MHz

HF/LF RADIOS:
HOMEBREW: 7 Tube+Rect 1v3 Regenerative RX for LF (built 2015)
Icom: R-75, Cascaded 250/125Hz CW-Filt, Panadapter. (~2009)
Icom: IC-7200 Xceiver, DSP IF & filters (~2015).
Kenwood: TS-450SAT Xceiver, cascaded 250/125Hz Inrad filters.
SDR: Softrock Ensemble II LF (built from a kit 2015).

ACC: HOMEBREW LF-MF Pre-Amp, MFJ-993B HF Auto-Tuner.
HOMEBREW 4 Port Antenna Multicoupler, Feeds 4 RX's.
AF Filters: Timewave DSP-599zx & HOMEBREW 8 Hz Filter.

ANTENNAS: 88 foot Long Ladder-line fed dipole, 35 feet AGL for MW/SW.
Active Mini-Whip, 36 Feet AGL for LF/MW/SW.
37 foot "Low Noise Vertical", 11 feet AGL for LF/MW/SW.
Cushcraft AR-10 Ringo at 14 feet AGL for 10M beacon.

From: Leonard Meek
Topic: 26974 Message: 27012

That's what I suspect, Jim. I would think if I added a tuned circuit to the output of the oscillator, I could tune it to one or more of the harmonics. Crystals are new to me (or vice versa) so I don't really understand the markings. Some of them are actually labeled "Overtone." Others have a crystal frequency and a channel frequency marked on them, mostly FT-243's. What I need is a tutorial on crystals, in one sylable words.

Leonard

27013. Denco Coils

Yahoo group: regenrx (2016 — 2017)
Date: 2016-09-18 21:42:20 UTC
From: jod2005@...
Topic: 27013 Message: 27013

When Denco were making coils they had a transistor range (blue for rf) and a dual purpose range (green for tubes and fets). Both these sets covered the same tuning ranges. Can anyone explain in easy to understand terms why they would be constructed differently for use with the same capacitor for the same range?

I understand that tubes and fets have higher input impedances but don't understand how that would impact on the structure of the coil. Has it got anything to do with internal capacitance of the active devices?

The Denco literature for Transistor and Dual Purpose Coils both state that for Range 4 for example, the range covered is 5 - 15 MHz and the Inductance for each is the same at 2.9 uH.

So what is the difference?

John

27014. Re: Denco Coils

Yahoo group: regenrx (2016 — 2017)

From: jod2005@...
Topic: 27013 Message: 27014

Well it would seem that nobody would like to contribute to this. The reason I ask is I obtained a box of 15 Denco coils, only white and yellow mostly range 5. I think these coils were used mainly in superhets. Today I wouldn't use these if I were building a superhet but opt for Toko coils instead.

So I want to rewind them for regens. I'm building Charles Kitchins High Performance Regen and intend using these plugin coils for various bands. I've already done one for 20 meters and the result is very good. But the fact that there were different coils for transistors and Fets puzzles me. Perhaps if I knew what the difference was I could even better results.

John

BJTs have a low-Z at the base, that's the reason why link coil or coil taps are needed to connect the base onto a tank circuit. BJTs also have a much higher transconductance than FETs does, coils for BJT Armstrong oscillator circuits have less tickler windings than coils for FET Armstrong type oscillator.

27017. Re: Denco Coils

From: Philip Hobson
Topic: 27013 Message: 27017

The difference is likely simply the tapping point of the coil as bipolar impedance is much lower than for tubes/valves and fets.

From: Bill Higgs
Topic: 27013 Message: 27018

John,

Not entirely sure on this, but an older Radio Communications Handbook (British) from 1971 shows a transistorized superhet with Denco coils in the front end. The coil has three windings: an untuned antenna winding (low impedance), a tuned winding, and an output winding. I'm guessing that the difference between the transistor and FET coils is the impedance of the output winding: lower for the transistor, and higher for tube grid/FET.

From: Richard
Topic: 27020 Message: 27020

Does anyone have experience with it? I just acquired one and am finding many bad parts - it must have been very wet. Of interest, it is usable to 63 Mc, and the grid leak resistor is merely 150k Ohms, a very low resistance for grid leak. My theory is it's necessary for stability (no super-regeneration) at VHF, but recovered audio will be low.

This may be old news, but since I am an old movie fan (in more than one sense of the word), I thought it might be of some interest.

In the circa 1995 remake of Billy Wilder's 1954 film "Sabrina", starring Harrison Ford and Julia Ormond, there is a genuine Eimac 304TL sitting on Harrison Ford's desk, seen in 3 or 4 scenes. As I said, could be old news, but it was new to me.

Far better than just a "Good flick"! It was many years ago when I saw it in a theater. The talk here makes me want to renew that powerful experience.

Charles

NetFlix does not have it but they have a description and it sounds interesting. If enough persons put it on their list they might make it available. It should be inexpensive for them to get that old movie.

I just discovered that it's also on Youtube (at least at the moment).

Once again, thank you, John. I'm looking forward to watching this
classic. Any film that features our beloved BAs is a special treat.

Gosh, it was 1945, 20 years before my first ham license, when I only knew one meaning for boat anchor. The film is an historically accurate drama. A 720-word NY Times review can be found at:

Looks to me like National NC-240, Hammarlund SP-200, Hallicrafters SX-24 seen in movie, and one corner of a National HRO.
Not sure what the radio is in the spy home lounge.
Dietrich’s radio shack (36:46) though is a bit overdone; 2 expensive National NC-240-D’s, a Hallicrafters HT-4 500 watt AM/CW
transmitter, with the audio preamp on the operating desk to the left of the receiver. On top the transmitter is a whip antenna
loading coil, so i believe the transmitter would have to be the Army version of the HT-4, that is, BC-610. Nice spacing on the
open line antenna feeder. In an earlier scene, where he’s uncrating the radio parts, he handles a transmitter PA coil for the
BC-610. Probably in real life Dietrich would have picked up a second-hand Hallicrafters receiver and built a transmitter with
something like a single 6L6 in the final.
Two cases i am aware of where German agents transmitted from North America, from Quebec and from upstate New York,
the transmitters were German Navy portable sets with about 20 watts output. I always wondered how those could be depended
on to reliably reach back to Hamburg, especially considering the transmit antennas were necessarily a lot less than ideal. I always
wondered if in fact there was some kind of relay station, or system, at work.

The Nationals are NC-200's. Right above the tuning knob the '200 has the NC logo. the '240 has a round logging dial.Didn't see a HRO but did see a little Howard 5 or 6 tube model and a Collins TDO.
Good detective work!

And the 240's have the decorative "feet" that the 200's do not have.

It's fun spotting this stuff in old movies. I've gotta watch it again to see what I can find....

The TDO – is that the rig on the FBI desk that’s used to call the cars?
To the left of this set on the desk, i think you may see the right portion of an HRO with the dial or partial dial showing.

Or, i’m imagining it.

The Nationals are NC-200's. Right above the tuning knob the '200 has the NC logo. the '240 has a round logging dial.Didn't see a HRO but did see a little Howard 5 or 6 tube model and a Collins TDO.

Good detective work!

No it's that BIG TX in the background @ 37:27. Pair of 805 modulating a pair of 813's.
As I see it on the left table is a HT-5 (speech amp for HT-4) and a NC-200 w/spkr.
Right table BC-939 (ant tuner for BC-610) early BC-610, Howard 400 series rx, NC-200 w/spkr, HB ant tuner on ceiling, and a BC-614 (speech amp for BC-610.
Don't think the transmitter is a HT-4 as it has the mil tag on it

The calling all cars tx is unfamiliar to me looks to be military but uses a D-104 mic? Most of the mil sets from WWII I've seen use carbon mics.

The TDO – is that the rig on the FBI desk that’s used to call the cars?
To the left of this set on the desk, i think you may see the right portion of an HRO with the dial or partial dial showing.
Or, i’m imagining it.

Thanks for posting these movie notes. Especially the note about The House On 92nd Street. I have been researching and building recreations of the very early German Adapter sets. On testing I discovered they were very practical and can reach out easily in fair to good conditions. I have read books and bought movies on the 1930s/40s spy game (, both sides) and this adds to my arsenal. I tried to buy a copy of the Movie Kontakt. So far no cigar. But perhaps the house on ..... will be more relevant to my research. Any other ones anyone knows of?

The fate of high tech U'176 submarine was probably sealed by the Cuban radio technicians that located a German spy transmitter in the Old Havana District.

The U'176 with all its 53 crew went down in 1943 after sinking several cargo ships that were transporting sugar and molasses as well as other key product like sulphuric acid for the nickel plant built by the US Government in Eastern Cuba. Cuban Navy Submarine Hunter PS13 was directed to the location where U'176 was located by a US NAVY amphibious Kingfisher that used wing wags to spot the place in very clear waters where the submarine was starting an emergency dive that did not impeded the sinking by the well done attack by the PS13 small wooden submarine hunter...

It was never found out if the spy sent his transmissions directed to the U'176 telling about port activities and departures of possible targets was the submarine as it was sailing around the Caribbean, or actually contacted Germany from where U'176 received the messages .

There is a book in Spanish about Emil Lunning, the spy that was executed by firing squad after all evidences pointed to him as the cause of death of tens of Cuban and American merchant marine sailors sunk by U'176.

Seems like the spy used a very up to date transmitter and receiver, and he was well trained to transmit CW Morse Code radiotelegraphy...

Glad you liked it.

I had to take a look. It's a very good "yarn," as they used to say. And at least one of those Hallicrafters sets is one of their lesser-known VHF AM/FM sets, either an S-27 or S-36. It looks like both the FBI and the Germans had one!

One of the hazards to submarine activity off the coast of the USA, and perhaps Cuba, was shallow water. When you cannot dive deep you are very vulnerable.

Here is the spy transmitter just for interests sake. Built in a wall socket box and it even has the plug in plate so it can be hidden in a wall totally disguised till required . Then using a normal 1930s/40s home radio the audio output tube is removed and the sets umbilical cord plugged in. The audio tube then is plugged in the box , the antenna hooked up and a key of some sort connected and you are on the air. If the host radio has short wave then a pair of hi imp earphones connected across pin 5 and 8 of the plug will give audio as well and as long as MCW (or AM) is being sent to the agent he is good. By putting a gimmick cap (twisted pair of unconnected wires) around the cap and around one pin of the IF tube a psuedo BFO can be rigged up not unlike what was normal for a S-38 com set. While not perfect it does work to a usable point although MCW which was fitted to many German and Allied transmitters is really the perfect solution. Some adapter sets are said to have plugged in directly however you discover very quickly this limits the host radio you can use to very few so with the umbilical cord plug in any radio using a beam power tube, even 1930s battery sets can host this adapter and operate well. With this set an octal 7AC or 7S pin out is required but that was standard fair back then. In fact all the old radios I have plus all the ones in my brothers collection will and have operated this adapter TX. My first contact about 3/4 of an hour after completion was with Phil, WB4FDT which is a decent distance from here. Anyway interesting subject to me and thanks for all and any info on movies or books about spy activity in North America just prior to WWll as we know it.

Leonard wrote:

> Many of the crystals I was using were nowhere near the freq stamped on the case.

As others have mentioned, one reason a crystal may oscillate at a frequency other than that marked on its case is that was processed to operate on an overtone, rather than on its fundamental frequency.

I recently encountered this when I borrowed the "12100" crystal from my Allied A-2516 receiver and installed it in a Pierce oscillator to convert the amateur radio 10-MHz band down to 2 MHz. In my circuit it oscillated near 4 MHz! (The A-2516's first conversion oscillator uses the Miller circuit--tuned plate, crystal grid--and so rejects oscillation modes at other than 12.1 MHz for that crystal.)

A similar hazard with an "aperiodic" (untuned) oscillator like the Pierce is that depending on the feedback capacitances in play--C from oscillator triode grid to common and C from triode plate to common--may cause a crystal processed for oscillation on its fundamental to operate at an overtone instead. I have a 3400-kHz HC-6-cased crystal that was well-behaved in its original Pierce application but oscillated very nicely at about 10.3 MHz in another.

Crystals commonly also have resonances other than their fundamentals and overtones; if a particular circuit happens to allow or enhance operation at one of those, you may be in for even more interesting figure-out-the-frequency adventures!

Best regards,

Dave

About 25 years ago I read in the Houston Chronicle a story about the local Houston Submariner Society. The group got formed right after WW2 in Houston and to become a member you had to have served in Submarine duty. The group had a Commander. But what was very interesting, he had served in submarine duty within the German Kreigsmarine. (Can't remember his U-Boat number.) He told the story about how his U-boat was stationed in the Gulf of Mexico and was positioned many times just off the coast near Houston. He was impressed with the night skylight of Houston which he could observe from the u-boat. After the war ended he immigrated to Houston as a resident and later became the submarine society's commander.

My father was a Lt. in a US Army intelligence group. However I had a relative, Captain Rudolf Bahr who was captain of U-305. His boat was sunk in the Atlantic in the beginning of 1944.

>I had to take a look. It's a very good "yarn," as they used to say. And at least one of those Hallicrafters sets is one of their lesser-known VHF AM/FM sets, either an S-27 or S-36. It looks like both the FBI and the Germans >had one!

>Posted by: john ruccolo <jr6v6gt@yahoo.com>

BTW, if one cares to read such stories, there's a book "Agent 146" that's pretty interesting. Erich Gimpel and a turncoat American were landed from a U-boat

in 1944. The story is actually much more interesting, i thought, than the "House on 92nd Street" story because "Agent 146" is by Gimpel, told from his

viewpoint. He was constantly on guard and always in fear that some little clue, like his unfamiliarity with American restaurants or some hint of an accent would

give him away. At some point he found love with an American woman but he had to keep his secrets from her too, and eventually he had sadly to just

disappear from her. Eventually he was captured and sentenced to death, but due to an obscure law forbidding executions during the official mourning period

for the American president, the execution was postponed, and then Germany surrendered, and execution was postponed again. Gimpel served a few years and then

was deported to Germany – so it's just strange twists of fate that saved his life. He even served time in the famous prison Alcatraz, where he socialized with

imprisoned Mafia bigwigs. You can see that his story has more elements that would make for a good movie.

Unfortunately the book has absolutely minimal details about his radio procedure. No receiver is ever mentioned. At one point he goes shopping for a 6L6 tube

for his transmitter, and is wracked by fear that even this will give him away. It occurred to me that he probably arrived with only the crystals he needed and the

telegraph key, which might be suspect items to be shopping for, in 1944 U.S.A. Buying a shortwave receiver would be another challenge and also probably one

that he would be fearful to attempt, so maybe he was already supplied with some simple small receiver. Another book on the Gimpel story by another author

states that Gimpel was to build his own 80-watt transmitter once in America, so if it used 6L6's, i think he'd be using at least two; or who knows, maybe he was

to build something like like the 'adapter set' Don mentioned which plugged into a receiver's output socket. You have to wonder how he could expect to reach

Germany reliably using makeshift antennas from New York city locations. Unfortunately that information is now lost; apparently Gimpel passed away in 2010.

The “Agent 146” book is a republishing of the earlier book “Spy for Germany” and is available in paperback at low prices.

There was a movie made about the Gimpel story, “Spion Fuer Deutschland”, which i recently ordered, along with “KLK an ZTX” (“KLK calling ZTX”) about the

“Red Orchestra” spy network working in Germany. Both movies are unfortunately for most U.S. viewers available only auf deutsch, no subtitles. And they may be in

PAL format, which means a learning curve for me and a bunch of steps i don’t relish, to convert it.

Thanks for the info, Dave. I suspected this was the problem. I had built a simple crystal tester, basically a Peirce, to test them and found that most of them were oscillating at some sub harmonic of the marked freq. So I built another tester, sane sirsuit, with a tunable tank on the output which could tune to various harmonics. Worked fine, but now I have to redo my regenodynes to select one of the harmonics. They may already be doing that to some extent, but results are not predictable. Good thing I didn't scrap the crystals.

The main Mother station for Germany was the German Embassy in Washington and you can find stories of the precursor to the FCC making raids there and see some of the photos taken. HRO receiver was in common use by them (bought third party style)as were some clones of a sort. I can get the link if you like from the fellow who showed it to me. A lot of activity was pre WW2 which for us started 1939 and 1941 for US. I am beginning to realize a lot of clandestine activity may have preceded those dates. So operating from eastern Canada and eastern USA would not be hard. Also U boats on the east coast and into the St Lawrence are a matter of record. The adapter set complete will fit in the toe of a work boot . A 6l6 gives a bit more wack. I have tried it on mine. It definitely liked it even without more V. Most host sets had a 6F6 or 50L6. Usually any with shortwave were 6F6. Occasionally you find a 6v6 but mine did like the 6l6 immediately. 300 to 400 miles is normal everyday conditions is possible. With the Shortwave sets you can steal the audio as I said with phones and the radio functions remain intact when not transmitting except of course Audio PA which is now the TX by way of the adapter set. The advantage of using the Host set if it was SW for listening would be no accidental signal from an over advanced regen control. I was surprised how well it worked. I was ready for it not to work if you know what I mean. I am going to look for those Hue. Thanks for mentioning them. I got into this subject accidentally and found it much deeper then I ever would have dreamed. I didn't know anything about it before.
donVe3LYX
The whole adapter set wires and all is in the toe of this boot but you cannot see it. Whether that was what he used or not who can say. Usually pre 1940 though probably.

I’m always interested in leads to check out in the general topic of clandestine-spy radio or prison camp radio and such.

I read somewhere that a movie of the book “They Fought Alone” is in the works – about the stay-behinds who hid out

from the Japanese in the Philippine Islands. If such a movie does come out i sure hope the communications aspects are

not totally unrealistic.

I had forgot that the German embassy could be the relay station at least into December 1941. After that, i still am puzzled

as to how Gimpel’s transmitter and random wire antenna in the big city could reach Hamburg. A U-boat could possibly

relay, but his transmit times would have to be somehow coordinated with the U-boat, and he could not be expected to

easily meet prearranged schedules.

Around 25:00 for the Germans and 1 hour 17 min for the Feds.

In shadowy lighting these could be mistaken for the more-common HF sets, SX-24 or 25.

I was advised by a clandestine radio expert in Germany to read the book Two Eggs on my Plate by Olaf Olsen. He said even though it was about an Allied spy it would give me excellant insite into how these type of agents operated and what they reported on. Shipping traffic was the no 1 info (which is why they were here as it goes right by in plain sight heading for the Atlantic and points along that route.) Schedule and freq is already carved in stone and sending the data seemed to be the priority. I don;t know if I would use the term relay station for any of them. I think that was where the message stopped and started , especially the Embassy one. The article said as late as 1945 it was still operational. Anyway here are two of the links Carl gave me.

Don – thanks for the link to the interesting doc.

My comments:

Embassies were closed shortly after declaration of war and embassy staffs were returned on neutral country ships.
There are 2 editions of “Two Eggs on My Plate”. The earlier edition has photos showing the “Paraset” in operation. (So this discussion DOES relate to regens, as the

Paraset receiver was 2x 6SK7 if i remember correctly.)

The CIA doc in the link below doesn’t mention the Erich Gimpel (“Agent 146”) story. I think at that time, 1944, there were maybe no more ways to get mail to

Germany, or they realized that any mail via a neutral country would be inspected, so maybe that’s why they tried radio again.

You are welcome Hue,
I had a look at another site but didn't save it. This info came from my friend Carl Gregory. If I remember the other one I will just tag it on the end of a post with HM after it.
Yes I understand that from your perspective however remember that for us in VE land the war was going since 1939 so what would be closed when you entered was very active when we were first involved. In fact my Dad got his notice in 1939. how I got into this was a German fellow showed up here in our county kind of out of the blue late 1936. he hung around my grandparents farm and was friends with my family. He was murdered in 1939. I was digging into his life a bit and discovered he was considered a war hero in his hometown and that German immigrants who came many years later knew all about him. The more I dig the more suspicious I become. And to be honest if he was just reporting on shipping and such pre 1939 that would not have even been illegal. There is an awful lot more to that story then I can tell here.
re Oluf Olsen Yes the copy I have of the Two Eggs has the Paraset in it. My friend Jim VE3DCX has a paraset as does T Hoeppe in Germany. After building the last transceiver which was inspired by the Weskit BN1 but is not tat circuit and seeing how well it worked both TX and Regen I went looking for one tube spy radios and that is how I stumbled onto the Adapter Set. And that started the "what was he doing here" question and it snowballed from there. I have fooled around quite a bit with listening for the regen on a nearby RX. Different circuits show quite a difference in telltale signals. It is surprising how much difference. Some you could run right nder someones nose and they might not find it even when listening to CW. others would get you killed back in the day under any condition. Anyway interesting subjects. Big interest in clandestine stuff all of the sudden.

From: msalbert@...
Topic: 27056 Message: 27056

Spotted this today, IIRC someone here was working on regen kits for kids, needing low cost audio amplifiers . . . seems like a good deal so may be useful

http://www.goldmine-elec-products.com/prodinfo.asp?number=G21097&mc_cid=d1014cf2fc&mc_eid=073d97384e

17 cents each! However the part appears to be a bit of a power hog (quiescent current is 40 to 55mA) so may not be too suitable for a 9V battery operated set.

I've no interest in the vendor, just a satisfied customer.

Regards,
Mark KB9VKE

That's Electronics Goldmine. They're pretty good. I've bought a lot of stuff from them. Another one is Dan's Small Parts, though he's not as easy to deal with. There's not as many surplus dealers as there once was.

thanks for the heads up....but that
KA2206, 2.3Watt Stereo Power Amplifier IC... at $4 is not so cheap and
it is SMD
which I consider to be a big NO-NO when playing with newbies.
Also... it IS stereo.

I can stick with $1 LM386 amp kits and also TDA2030A kits......
EBAY:
TDA2030A Electronic Audio Power Amplifier Board Module Mono 18W DC 9-24V
DIY Kit
costs $1.60 and is VERY LOUD.... presentation... auditorium.. loud...
running on two 9 volt batteries in series.

So I have found headphone, desktop, and presentation amplification can
be done for $1.60 or less.

Sorry I didn't notice they were SMD (looked so big in the picture!). For $4 you do get 24 chips so the cost is low. But being SMD and too much power, yup probably not suitable for your application . . .

There is still an embargo of electronic goods to Cuba, you need to be
patient until it's lifted, it will not be long as they are setting up
ambassadors soon.

Looks like a pretty nice parts package!
Now, are you sure this was rejected by the U.S.P.S. ?
I ask, because the form to the right doesn’t look to me like a U.S. form, and it’s only in Spanish and French.
Odd, isn’t it? It’s actually easier, less red tape, to travel to DPRK than Cuba, and DPRK is a scary place.

Was the package returned by USPS or Cuba post? USPS and USCFR have info on the required paperwork for stuff sent to Cuba.
Requirements differ for commercial and personal goods so it's important to be clear in the description.

I sent a package (a few HC-49 crystals) to Arnie at the beginning of the year.
It arrived after 3 months. I live in Australia.

Before this I wrote (ordinary letter) but I think my letter was dumped or lost.
It didn't arrive.

I sent the package of crystals as a "letter", not a parcel.

Topic: 27056 Message: 27067

I bought several LM386 modules from eBay.
I got two 'styles'. In one, the volume control is a trim (screwdriver) pot.
The second had a conventional volume pot, a 3.5mm jack (for input) and a DC power connector.

I haven't tested the second item, but looking at the board I suspect the (volume) pot works in "reverse" ie CW is minimum volume.

I wanted to see how much power I needed to drive a speaker.
Answer: It depends on the size of the speaker!
Small speakers are inefficient. The results below refer to a 10 inch speaker 'rescued' from an electronic organ.

LM386 amplifier module. Sensitivity.
Using a "large" spkr (eg 10 inch)

Signal to speaker.
30mV use-able output in approx 100uW
quiet conditions

60mV listening in bed volume 500uW

90mV quite useable volume 1mW

200mV loud enough to hear across 5mW
the room when no other noise.

400mV loud enough to use 20mW
on the work-bench.

500mV reference level. 30mW
700mV reference level 60mW

Using a small speaker (from a PC) I got no use-able sound below 100mV.

27068. Re: cheap audio chips SPEAKERS are NOT created EQUAL

Yahoo group: regenrx (2016 — 2017)
Date: 2016-09-28 22:23:52 UTC
From: Rob
Topic: 27056 Message: 27068

All of my speaker experiments were done with loose speakers, nothing in
a mounting or cabinet.

I do not have numbers like you Les but I have had some very interesting
revelations here about
multiple speakers.

The goal being to come up with something for the kids to build I bought
cheap 8 ohm 3 inch speakers from
ebay....4 different kinds , then built an amplifier.. and hard wired
the speaker:
http://www.learnmorsecode.com/amp/tl431PCBdone1.jpg

I did this with two different designs

http://www.learnmorsecode.com/amp/tl431.html

and then
resorted to using wire wrap pins as plug posts instead of using up the
speaker supply here.

I really was surpised at how quiet these speakers were.... so I swapped
out the speakers where I built pin instead of hard wired speakers.....
and found that no two speakers sounded the same
and all were unacceptably low volume..... would be fine for
headphones... but not for desk top audio.

My REAL problem was that all of my amplifiers really need to be having a
high impedance buffer between my experimental amplifier circuits and the
716 regen circuit and they all really did come to life once I added the
darlington pre-amp circuit......

BUT
talking about speakers here......
even after I did add the darlington I ran through the same audio tests
and concluded that
the 3 inch speakers really did suck compared to using a 10 inch speaker.

So then I tried a few high end speakers.... car steareo speakers.... and
they didn't sound any good at all.....
not nearly as loud as the simple Radio Shack 8 ohm speaker meant to be
used in a bookshelf speaker.

This lead me to believe that all of my tiny 3 inch speakers need
something... perhaps some more research will reveal
circuit errors I made ......
or not....

because the large speaker sounds great.

My amplifier circuits were a variety from scratch built LM386 and
descrete components .....

I didn't just use an LM386 kit.

From: Bry Carling
Topic: 27076 Message: 27076

Why are you bothering with chips at all?

You can buy a complete amplifier ready to go in a small package, usually with a volume control included, for a buck or two on eBay. Generally these are more up to date and will sound a LOT better than those LM380 and LM386 noise makers that most QRP home brewers tend to love. Add power and speaker and you are good to go.
No muss, no fuss. I bought several of them in the past year and all work great.

73 - Bry AF4K
Posted by: msalbert@... kb9vke
Date: Tue Sep 27, 2016 2:24 pm ((PDT))

Spotted this today, IIRC someone here was working on regen kits for kids, needing low cost audio amplifiers . . . seems like a good deal so may be useful

http://www.goldmine-elec-products.com/prodinfo.asp?number=G21097&mc_cid=d1014cf2fc&mc_eid=073d97384e

17 cents each! However the part appears to be a bit of a power hog (quiescent current is 40 to 55mA) so may not be too suitable for a 9V battery operated set.

I've no interest in the vendor, just a satisfied customer.

Regards,
Mark KB9VKE

WHICH did you buy?

I have 8 different complete amplifiers... all SMD... not kits.... some
are mono...some are stereo...
that I bought to experiment with their usefulness and feasibilty of
newbie radio applications.

As you said...
Add power and speaker and you are good to go. No muss, no fuss.

BUT
I wanted to find something that was simple enough for the kids while
giving enough hands
on experience for them to "own" it..... not just be another mystery box
appliance they got as a gift like their
smartphones that they don't test or probe with meters or scopes.

The $1 LM386 kits are through hole components so there is no SMD crumbs
to lose.

27078. 400 volt zener power supply for geiger tube

Yahoo group: regenrx (2016 — 2017)
Date: 2016-09-30 19:23:54 UTC
From: Rob
Topic: 27078 Message: 27078

I stumbled onto geiger tubes and instructables.com instructions
how to build power supplies for these geiger tubes.....

the PDFs:
Simplest Geiger Counter
by tanner_tech on September 8, 2016

and

Homemade Geiger Counter
by electric_piano_5k on March 15, 2011

picture of geiger tube:
http://www.learnmorsecode.com/geiger/geiger.jpg

Its not that I require any geiger counter right now to detect anything
nuclear......

MY INTEREST in these circuits is that they both describe build a battery
operated
power supply out of a 555 timer pulsing a transformer to get 1,000 volts
and then
using 100 volt zener diodes stacked to create a 400 volt voltage drop
across the
zener which is then fed into the geiger tube.,,,,,, requiring very
little... 10? miliamps.

sooooooo..... just wondering.....
is it feasible to use this method to make 100 volts for regen tube
receiver circuits?

Two schematics here:
http://www.learnmorsecode.com/geiger/geiger2.jpg

this one is fuzzy
http://www.learnmorsecode.com/geiger/geiger4.jpg

now....along those lines..... I build a circuit from a FOREST MIMS book
about 30 years ago
that ran on a 9 volt battery and made 220 volts:
this circuit:
http://www.learnmorsecode.com/geiger/hv.jpg

Is it so farfetched to think this type of circuit can power a vaccuum
tube receiver by adding
the zeners and some smoothing capacitors?

27079. Re: [regenrx] 400 volt zener power supply for geiger tube

Hi,

Why the need for zener diodes? Unless you want ultra stable or specific voltage just smoothing the pulses with RC combination would probably do for Rx H.T.

Will

I'm not real clear on what this sentence means:
smoothing the pulses with RC combination would probably do for Rx H.T.

The normal RCRC combination used after any rectifier circuit.

Something like a 47 ohm R to limit the current through the rectifier.
then a 10 or 22 micro farad 600volt Electrolytic capacitor. Follow with
another similar stage, with probably a bigger resistor depending on how
much voltage you have to spare. it would further reduce the ripple from
the sharp spikes that pulse transformers produce.

Depending on the frequency of the pulses it might be possible to reduce
the value of the capacitors. Either or both resistors could be replaced
by a choke. It would not need to be as big as would be used or 50 or 60
hertz.

The only thing the zeners do is stabilize the output voltage at the
expense of using a few milliamps of current. It is not usual to run
recievers off a stabilized supply apart from maybe the oscillator circuits.

Most radio electronic handbooks would have information on rectifying and
smoothing power supplies. You would need to adjust the capacitance
values to take into account the higher frequency. Something like an old
vibrator auto radio supply would be similar.

Cheers,

Will

Hi Rob, most GM tubes don't require much current, a few microamps maybe. Very roughly, they are "charged up" like a capacitor, then discharged by the radiation. That discharge is passed through a high-value resistor, then amplified to make the characteristic "clicking" sound. So HV current needs are very low; for most GM power supplies even a DMM will be too much load and crash it. One circuit you mentioned uses a push button to generate HV pulses to charge up the GM tube, which can then operate for quite a while. The Boys' Second Book of Radio and Electronics by Alfred Morgan has a project How to Make a Geiger Counter for less than $15 (1957) used the same HV technique. He says it "proved sensitive enough to detect the radioactive fallout which reached New York City from atomic bomb tests in Utah". I found a brief description of it here.
http://covingtoninnovations.com/michael/blog/0408/index.html

Probably there are a some GM tube HV supplies which are overbuilt and can do what you want. I've had good luck with nixie tube power supplies; several watts of power are possible in a few square inches. Depending on the design some extra effort will probably be needed to make them suitable for radio use. The inductor is a major source of RFI; changing to a toroid helps. One prebuilt module used an unsuitable electrolytic filter capacitor; it ran warm. Changing to a film type fixed it. I have not tried them with regens; maybe you'd need extra effort like shielding and feed-thru caps to get the switching noise down.

Regards,
Mark KB9VKE

2017 Novice Rig Roundup progress

Good news - ads are going into a lot of the major ham magazines.

The rules have been updated for 2017 to incorporate most of the requested changes.

The FAQ changes will be under way today.

The WEB BASED log-entry system will be up and running soon. Alternative for those doing paper logs is that you can scan it and send in a scanned LOG via e-mail with claimed score.

The SOAPBOX for 2016 NRR is WAY BEHIND due to having to fulfill all of these other roles. I will try to post it soon.

Thank you to those who contributed to the budget for NRR 2017.

PASS THE WORD! Send out flyers!! Send them with your QSLs. Sne dthem with your e-mails! Take them to hamfests! (I will be planning to give them out at the Melbourne, FL hamfest next weekend.)

Please download the flyer! Print them... use them!!

The flyer is here:
http://af4k.com/imag/ham/NRRadd2.pdf

Get your rigs ready!! There is going to be a huge turnout for this 9 day event in February my friends!!

73 de AF4K - Bry
Co-chair, NRR 2017

Wanting to build Kitchin Simple Regen Receiver, was looking for a 1N34A. Lots of them on Ebay, but there are so many copies of out of production parts. RS web said the store had them, the clerk said no. But in the parts bin were packages of "Germanium General Purpose Diodes DO-7" in the slot labeled 1N34A. Two in a package for $2.99, so bought a package. Now am wondering if a "DO-7" might be the same knockoff was trying to avoid. It says "replaces 1N34A".

Just curious.

Curt -

'DO-7' is the package style. Some Germanium diodes, 1N270 for example, are made in DO-7 cases.
I don't think 1N34As were ever made in DO-7 though. The true 1N34A was a point-contact diode
sold in a case with the ends soldered closed.

Most 'substitute' 1N34As are actually Schottky diodes, which are 'almost' as good as detectors
as true 1N34As.

A lot of good diode information is available on the <midnightscience> website, devoted to crystal radio science....

Dear amigos: The Russian made germanium diodes that were manufactured in the 1970's are among the best I have ever tested on crystal sets... The famous SELENA B-215 and VEF-206 receivers used them.

They may be available from EBAY sellers that are located in former Soviet Union nations... The diodes can be hand picked for best performance from a large lot, and you will find that the plant's quality control OTK was really very good, as the statistical dispersion of parameters is rather narrow...

BTW, using four of those germanium diodes in the QUADRUPLER diode detector circuit , and adding a bit of ¨spice¨, that meaning a minute forward bias, a crystal set of simply amazing sensitivity is achieved.

Hello Curt

Are you building this circuit?
http://www.arrl.org/files/file/Technology/tis/info/pdf/0009061.pdf
http://www.arrl.org/files/file/Technology/tis/info/pdf/0009061.pdf

Then make sure to use a genuine Germanium diode. Others are not working well in this kind of floating detector.

Best regard,
Bernd

Yes, that is the circuit. K7QO suggested building something in November, a simple regen being one suggestion. So decided an N1TEV design ought to work.

I have no way to identify a genuine anything among the fakes and counterfeits what with the Chinese busy marking/renaming cheap junk as high quality, flooding every market for anything.

So, will let the circuit performance tell me what is and what isn't genuine. I'll just test different diodes and see if any of them detect signals.

Don't know, if the link is working. I did real measurements some time ago, to confirm simulation results. A Germanium diode on a high impedance load of 1Meg ist working best. A Schottky diode is rectifying somehow, but the output signal is much smaller and shows distortion. A standard 1N4148 doesn't detect at all!

Dear amigos:

If you have access to a large number of D311 Soviet germanium diodes...
it is a worthwhile and entertaining task to test them one by one
connected to the actual circuit where you need to use it...
I have a question ... What can be gained or lost by using Schottky type
diodes as a weak signal detector ?

Also... in SPRAT the G-QRP Club excellent magazine they published years
ago a circuit for a crystal radio under the name ¨ QUADRUPLE DIODES ¨
detector... I have lost the original magazine... and now that so many
persons are once again motivated by the wonders of simple radios... it
would be nice to recover the circuit diagram.

BTW, the Kitchen floating diode detector is not as efficient as a
detector with a termination... !!!

I'm not an electrical engineer. I am a radio electronics hobbyist.
2 years ago....when I could not find real 1N34A diodes I did go down the Schottky diode path.
I experimented with a bunch of Schottky diodes found in example circuits all over the internet.
My test here was very simple.
I would set up my 1N34A diode bare bones crystal radio and listen to the local radio station
and then
swap out the 1N34A with the "new" diode and compare what I heard.

http://www.learnmorsecode.com/help/xtalbarebones.jpg
http://www.learnmorsecode.com/help/xtal1.html

this was truly a GO..NO GO type of test.... noting that I get ZERO reception here in my box canyon
location of anything more than ONE local radio station during daylight hours.
And that station is a preacher screaming non-stop fire and brimstone crap and once in a while he takes
a break from preaching and tries to sell you investment opportunities in gold.

So my disappoinment level was pretty high.
Even if I could hear something on my crystal radio I didn't LIKE what I heard on my crystal radio
and I could not justify kitting these for scouts if all they were going to hear was this one dick.
Thats why I switched to researching regenerative receivers.

Back to Schottky....
what I found was that silocon diodes like 1N4148 were silent no go....
as expected.

I found that most Schottky diodes that other people raved about working great as
a 1N34A replacement.... WOULD receive the local radio station..
BUT
the audio range was sort of crunchy.... would clip on the highs and left out the lows.
This was strictly a hearing test for me.

I concluded that if I wanted to make a project for the kids to do desktop to desktop
wireless Morse code transmissions then YES... the very cheap and readily

available Schottky diodes
would work
BUT
I would not want to have a kid go to the trouble of building a crystal
radio around a Schottky
diode looking for real music radio stations.... IF I could give that kid
a cat whisker germanium diode
that outperformed the audio crunch of the Schottky.

again... I am not an engineer.
this was stricly hobby observation.....
so if anyone is building great sounding Schottky crystal radios then
please share your schematics.

The ones listed as D-18/FO-125 ex-USSR Germainium Detector Diode from a Ukrainian vendor on the auction site are 6 bucks for twenty and 7 for shipping. They have a neat vintage look, are a good deal and seem to work very well up to at least 12mHz in an AM/SW crystal set and as a detector w/Q multiplier similar to the Kitchen set.

Cheers,
gb

Hola Arnie y otros radioaficionados –
I'm glad this subject of the Russ diodes came up, and i'm going to buy some. I also like it that they are visually interesting!
Now – i'll see if i can get a SPRAT DVD with the schematic and if i do, i'll get the schematic to you. I hope it's not just a fullwave bridge (4 diodes)
because i found that not as good as the fullwave voltage doubler. I believe the back resistance or capacitance of the 2 diodes not being used
on alternate half cycles loads the tuned circuit.
You mentioned a 4x voltage multiplier crystal radio and i don't see how that can work into an actual practical load resistor where power, not
just voltage is required. The doubler does work because it's just using both halves of the cycle.
For crystal radios, i know Schottky diodes have been touted, but i never found them as good as good germaniums.
Also – using a piezo headphone, like the Brush company of years ago – the floating diode is just as effective as the conventional circuit. It's kind
of amazing, but true!
Unfortunately for crystal radio DXing, we have 2 local stations and 2 weather and sea conditions broadcasts on the MW band here, then the
next MW stations are 110 km away, and to dodge the locals takes very good selectivity.

AAZ18 is another goldbond diode, and seems to be available at low cost.

Looking up the specs, i learned only now that i had misordered and bought AAZ17, which is a different

animal, and that explains to me now why they didn’t work in crystal set radio.

In 1N34-types, germanium diodes, it seems to me that larger=better, in my experience. Some

old germanium transistors work just as well, i mean using them as diodes.

http://www.learnmorsecode.com/help/diodesmail.jpg

The D9B , 2AA113 and D311 are the Russian diodes.
Arnie speaks very highly of the big black D311 diodes.

The two marked unknown are real mystery meat to me.

ALL of these diodes (except the mystery meat) came from batches of
diodes... 50 to 200 diodes....which were tested and DID receive local
radio stations on my simple crystal radio two years ago.
I was preparing to kit radios for scouts.

When I ran into problems getting cat whisker germanium diodes I looked
into schottky diodes.
I never really was happy with the schottky diodes.... they just didn't
sound as good as the cat whisker diodes.
BUT
they may work great for you.... I was using them in a strictly bare
bones crystal set.
Note the blue diodes.......CDSH270.... I bought them from MOUSER.com
per THEIR advising me to use them instead of obsolete 1N34A diodes.
These CDSH270 diodes were by far the worst compared to the other
schottky diodes I experimented with.

I found that the 1N5817 schottky was a suitable replacement for 1N34A
diodes with very little difference in reception.
AND
just for fun.... sort of to show the kids how to make James Bond radios
.... I played with SMT 1N5822 schottky
diodes.

Noting that sometimes surplus reels of 5,000 diodes appear on EBAY
...... I grab what I can cheap.....
and then if it does end up in a scout project I know it did not cost
more than a buck to build a radio.....
since the diodes cost no more than pennies.
I just could not get that kind of massive price break with germanium diodes.

I am very interested in learning how to build better radios with either
the NOS germaniums or the newer schottky diodes.
It doesn't matter to me.... I now have a pile of both old and new.

27112. Mk.8

Yahoo group: regenrx (2016 — 2017)
Date: 2016-10-04 19:55:55 UTC
From: Leonard Meek
Topic: 14969 Message: 27112

After reading Mike Bittner's article in ER #328, I decided to take another look at my Mk.8. I agree with Mike, the regen circuit in the RCA tube manual is about the best. I like his use of a cascode RF amp. I may backfit my Mk.8 with the same circuit. My circuit uses an over complicated varactor tuning setup that doesn't perform well enough to be used in other sets. It helps a little on MF but becomes useless on higher freqs. Besides calculating various component changes, I added a pair of germanium diodes (ITT152071 because that's the first ones I came up with, but I guess any Ge diode will work) across the AF gain pot to cut down on some of the static I'm getting from my neighbor. I think it's from his motion sensors. Every time a car passes the house, all his yard lights turn on. Annoying. Sensitivity of the Mk.8 is quite good, judging by the number of weak signals it can pick up. As B. Weeber says, a stage of tuned RF ahead of the detector can do wonders. I may scrap all my other circuits in favor of this type.

Is the ER #328 article available online?
Will we have access to the update?

That matches my experience. I am resurrecting a McMurdo-Silver 801
regen which had been very wet, and installed a 2 inch speaker to replace
the missing 2 1/2 inch one. Comparing it with larger 4 inch ones it has
noticeably less output. However, in the circumstance it's acceptable.
The #801 is working now, but still needs help.

I tried to find the ER articles. Apparently only available
in the US as a minimum order of $10. Any chance as copyright
holder you could post the updated schematic here, Mike?
We could probably figure it out without the text of the articles.

What does ER stand for and WHERE is available..?? free or pay.. I don't
care..... I'm still stumbling over
WHAT we are talking about.

The MK schematics are always nice to examine. Thanks Les.

HI,

I have the RC-29 RCA tube manual (copyright 1973) and can't find any
regen receiver circuits in it. The only receiver circuits are
superhets. I suppose that I'd need to find an even older one to find the
circuit?

Coils are always a problem, but I don't think they're as critical as you might think. Some time ago I wound a set of coils on 4 pin forms, before I knew much about building regens. I didn't even know the inductance of the coils I was winding. I used a table from one of the "Short Wave Radio Manuals," 1934 or 1935. I think they were based in a varicap of 140pF. Since then I've used them with other varicaps varying from 80pF to 400pF. Of course there blanks and overlaps, depending on which varicap they're tied to, but that doesn't bother me much. The idea is to get the circuit working first, then worry about trimming it later. It's a good idea to wind a few more turns than you need. Then you can remove one turn at a time to get to the number you need.

Many thanks for trying to give us access, Mike; very much appreciated.
However, a GG account seems requisite to access the file.
No idea what this is or how to achieve it. If I had a soul,
I would happily sell its worthlessness to GG in order
to access such gems as yours...

Any other way to upload the schematic to a free-access site???

With solar emissions, invisible asteroids and comets lurking
to pounce, all this seems so infinitessimally pathetic...

Mike wrote:

> I hope you will share your Grounded Grid RF amp with us when you get around
to building it. I had thought of doing the same thing until I noticed that
V1B is functioning as a GG amp.

V1A and V1B are operating in cascode--that is, as a synthetic tetrode. You could replace them with a 6SJ7, suitably wired (connect its suppressor grid, G3, to common) and notice little or no difference in performance.

For a grounded-grid amplifier that works well at 7 MHz and lower frequencies--haven't used it at higher frequencies yet--see the first stage in the two schematics in my page at http://dpnwritings.nfshost.com/ej/wr/ http://dpnwritings.nfshost.com/ej/wr/ . Whatever gain the GG stage provides is incidental; its co-primary main functions are (a) to isolate the detector from the antenna and (b) to provide a dependably-low-impedance antenna input that supports the insertion of resistive attenuator networks to bring the antenna noise floor down to a level just above the detector noise floor.

I have RCA tube manuals RC15 and RC16. They show dates of 1947 (marked with my name with its juvenile penmanship) and 1950. The only difference I see is the latter's substitution of a 6K6GT for the earlier 6F6 triode connected audio output stage.

6SK7 RF amplifier with gain control in its cathode; 6SK7 Hartley regen with screen voltage regen control and a 300-500 Henry choke (ouch--unobtanium) as its plate output load; capacitor coupled to a 6C5 voltage amplifier, in turn coupled through an interstage transformer to a 500K potentiometer volume control with its arm connected to the power amplifier's control grid.

Charles

You're right. I just looked in my copy and it's not there. There's a site where you can download copies of all the tube manuals, but I don't know how to access it. Maybe one of the more computer literate members can guide you.

I am not a great fan of undue RF gain.
Dave, your GG design is the one which inspired my thinking,
not least because of its relative simplicity.

I agree with Leonard's comments. You can take the value in henries but then what? Has no practical value if you are sitting with a coil and a hank of wire.The more you wind the better you get at it. Soon itis second nature and you just pick up a form and do it. You will be so close it will amaze you. This week I needed a 40M coil on a one inch form. I took my best guess approach and wound it then checked it on my fet GDO with an average value cap across it. (56pf) It was right where I wanted it. surprised even me. I understand the nervousness. Sometimes also the fear instilled by the "overeducated and undernourished" can diswade folks from making a stab but really it is probably the easiest and most fun part of a build. As Leonard said put on too many and you can unwind one or two easily. And remember what worked so you can always do it. Boys have been doing it since Marconi first did the pond hop at Signal Hill. Not really as hard as one might think. I have given what I use to quick calculate before so I wont repeat it. But it does work every time.
I would encourage a try. You may be a natural at it.

Hi Don,

Winding practice is in itself "education" and I have not eaten anything while "making things" (supper excluded). I don't know I would be ragging on 'over-educated' or "undernourished" people if I had lots of hands on 'over-education' while forgetting to eat. In fact, I have been making things since I was about 6 years old and I am appalled at the number of people who do discourage creativity. The leading baloney I hear is "you need a factory" to make those - or three university degrees. We only need a factory to mass produce things. Making one or a few of anything can be done without a factory or a gov't nanny. Just *do* it. I encourage people to do things too.

There are some people who are over educated and have degrees in regen radios and also encourage others to make things.

I think the advantage of a tuned cascode amp over a GG amp is increased selectivity. The GG amp does match the low impedance antenna to the detector though, but that can be accomplished in the antenna coil.

Yes, but now the quality of those tools is far less, certainly in the case of Harbor Freight, than what you used back then.

The radio receives AM, SSB, CW using the RS2760419. Its laying on the bench now, so will need to put it into a box to stabilize the tuning cap adjustment. I have in mind then testing several different diodes to see how they compare. I'm using a dip socket to hold the diode.

Leonard wrote:

> I think the advantage of a tuned cascode amp over a GG amp is increased selectivity. The GG amp does match the low impedance antenna to the detector though, but that can be accomplished in the antenna coil.

Yes, tuning will impart more selectivity than no tuning. :-)

But you won't hear any affect attributable to the additional selectivity added by the cascode's tuned input unless signals far enough off channel to be knocked down by that broad additional selectivity are overloading your detector so badly that they audibly mar reception. (And again: There's no value to using a cascode there aside from it being a cool use of a dual triode. An RF pentode--say, another 6SJ7--will give the same performance at MF and at least the lower 2/3 of the HF. Only at the upper HFs and above may the somewhat quieter performance of the cascode be noticeably more useful--and that will be pretty much be only for CW/SSB reception, as you won't hear a quieter noise floor of you're using your regen in non-oscillating mode to receive AM.)

What a regen does _not_ need is gain between it and its antenna, as I describe in my 7120-kHz-receiver page. Hence my satisfaction with the GG amplifier and the addition of 15 to 18 dB of attenuation between the GG stage and my antenna system.

As to the issue of input selectivity and the grounded-grid amplifier, once you've brought your receiver's input impedance down to a level on the order of 50 to 75 ohms, you're set to insert all sorts of modern filtering in there. A two-tuned-circuit, "no tune" filter is an obvious choice; I have switchable 80- and 40-meter such filters built into a Snickers tin that I can put in front of my 80- and 40-meter regens, but so resistant are those receivers to overloading that I never need additional filtering even though I use my ham transmitting antenna for reception. (For an overview of what such filters are about, see this article cadged from _QST_ with poor attribution: http://www.robkalmeijer.nl/techniek/electronica/radiotechniek/hambladen/qst/1991/12/page29/index.html http://www.robkalmeijer.nl/techniek/electronica/radiotechniek/hambladen/qst/1991/12/page29/index.html . Some guy named me edited that article for publication way back when, so you'll see my name as author of one of its sidebars. (I especially like Zack Lau's 8-kHz-wide filter for 80 meters...)

I don't understand this bashing of the quality of Harbor Freight tools.

Perhaps you need something special. Not me.
I have walked into Harbor Freight and picked up a canvas tool bag and walked
around the store picking up screw drivers and wrenches and pliers and allen wrenches and filled that bag with tools
that added up to $40 and labeled it BIKE TOOLS so my kids and grandchildren didn't walk off
(ride off) with my tools from other toolboxes.

That same collection of tools would have cost me $200 at SEARS or LOWES.

We were talking about winding coils...making parts not so readily available now....

I said there is no difference in your garage bench work... or kitchen table... or factory......
when it comes to something as straight forward as winding a coil.....
the tools aren't so special.....
you can even get them at Walmart.

YOU CAN GET THE WIRE AT WALMART
http://www.learnmorsecode.com/rfcoil/index.html

I always had a problem with the mystery of measuring inductance.
I never had a grid dip meter so last year I bought a digital multi meter that did inductance.
Digital inductance meters now cost between $15 and $30 so there really is nothing under the hood
we can't measure in radio circuits now.

Yes, what _is_ this devilry of actually finding stuff out and then applying that knowledge to obtain a predictable result? Why aren't we _all_ happy with starting our cars like Fred Flintstone?

For those interested in knowing a bit more what they're doing in addition to just doing what they already know, here's a basic how-to about determining "how many turns" for a shortwave coil when an article doesn't give you that information.

Two online calculators will get us there. First, though, for those wanting PDFs of those various RCA tube manuals, you can get them from the tubebooks.org subpage at http://tubebooks.org/tube_data.htm http://tubebooks.org/tube_data.htm . The 1948 (RC15) edition of the _RCA Receiving Tube Manual_ includes an "AC Operated Shortwave Receiver" on page 220.

Now this article throws us the curve ball of specifying only a tuning capacitance (140 uuF, or 140 pF) for its tuned circuits. (This worked back when that article was published because you could go into any radio catalog--or radio store--and find ready-made RF coils specified to be used with such-and-such tuning capacitance.) But knowing that, we _can_ figure out coil specs for a first try.

So the first thing we do is assume that we have 130 pF, not 140 pF, just to make sure we've built in some leeway hitting resonance with whatever 140-pF-ish capacitance we happen to use.

And then we decide the lower end of the range we want to cover. Considering that the lowest international shortwave band with much action is the 6 MHz band. we'll make our radio start tuning right at 6 MHz.

What inductance--how many microhenries?--might that require for resonance with 130 pF? An online calculator capable of determining resonance from either angle--L or C--can help: http://toroids.info/T200-2.php http://toroids.info/T200-2.php . This happens to a calculator set up to find turns for a particular toroidal core, but as we use it we're also given _generic_ L and C information that will give us what we need.

So in that page we type 6 in the MHz box and 130 in the pF box, and press Calc. And we're informed that we need a 5.4-microhenry coil.

Now, assuming we don't want to use a toroidal core, we next want to know how many turns to wind on a pill bottle to get that inductance.

The calculator at http://www.crystalradio.net/cal/indcal.shtml http://www.crystalradio.net/cal/indcal.shtml can help us. Its "Solve for Turns" features seems to be broken, but we can use its default "Inductance" setting to do a bit of cut and

try.

We leave Solve set to Turns; type 1.125 into Coil Diameter; type a trial value into Turns (let's try 10); type a Winding Length (a length equal to the coil diameter is a best practice for technical reasons, so let's try 1.125 there, too); and then click Solve.

Huh, 1.93 uH. Too little. So we bump Turns up to 20 and Solve again. Hmm, a bit over 7 uH. Hey, we can get 5.6 uH with 17 turns. That's close enough to 5.4 uH for fun, and we will certainly hit 6 MHz with 130 pF with that coil. If we want to fiddle further, we can increase the winding length a bit to bring 16 turns to exactly 5.4 uH.

That's maybe ten minutes to figure out how many turns of wire we need to hit a certain frequency with a certain capacitor and a certain coil form.

Best regards,

Dave

Hello Rob,

I looked in my files and found this:

PCB Track width Vs Current Rating

Current width in inches
0.5A .008"
0.75A .012"
1.25A .020"
2.5A .050"
4.0A .100"
7.0A .200"
10.0A .325

However, I don't know if this applies to 1 ounce or 2 ounce copper clad board.

I'll look some more ....

Les

Hello Rob,

At least one source for the info I sent was a tutorial provided by David L Jones, PCB Design Tutorial.
He refers readers of that tutorial to www dot alternatezone dot com for the latest copy.

And in that table Mr. Jones gives the track width for both 1 ounce and 2 ounce copper clad board, and I can say that the figures you saw in my last posting apply to 1 ounce copper. If you use 2 ounce copper the track width can be halved.

I believe this info will help you!

Leslie

Leonard wrote:

> I think the advantage of a tuned cascode amp over a GG amp is increased selectivity. The GG amp does match the low impedance antenna to the detector though, but that can be accomplished in the antenna coil.

Yes, tuning will impart more selectivity than no tuning. :-)

But you won't hear any affect attributable to the additional selectivity added by the cascode's tuned input unless signals far enough off channel to be knocked down by that broad additional selectivity are overloading your detector so badly that they audibly mar reception. (And again: There's no value to using a cascode there aside from it being a cool use of a dual triode. An RF pentode--say, another 6SJ7--will give the same performance at MF and at least the lower 2/3 of the HF. Only at the upper HFs and above may the somewhat quieter performance of the cascode be noticeably more useful--and that will be pretty much be only for CW/SSB reception, as you won't hear a quieter noise floor of you're using your regen in non-oscillating mode to receive AM.)

What a regen does _not_ need is gain between it and its antenna, as I describe in my 7120-kHz-receiver page. Hence my satisfaction with the GG amplifier and the addition of 15 to 18 dB of attenuation between the GG stage and my antenna system.

As to the issue of input selectivity and the grounded-grid amplifier, once you've brought your receiver's input impedance down to a level on the order of 50 to 75 ohms, you're set to insert all sorts of modern filtering in there. A two-tuned-circuit, "no tune" filter is an obvious choice; I have switchable 80- and 40-meter such filters built into a Snickers tin that I can put in front of my 80- and 40-meter regens, but so resistant are those receivers to overloading that I never need additional filtering even though I use my ham transmitting antenna for reception. (For an overview of what such filters are about, see this article cadged from _QST_ with poor attribution: http://www.robkalmeijer.nl/techniek/electronica/radiotechniek/hambladen/qst/1991/12/page29/index.html . Some guy named me edited that article for publication way back when, so you'll see my name as author of one of its sidebars. (I especially like Zack Lau's 8-kHz-wide filter for 80 meters...)

I'm not real computer savvy, but I was able to enter the formulas for resonance, inductance, etc. into an Excel spreadsheet. So all I need to do is enter two parameters and it calculates the third. I use my sig gen and freq counter to ring a coil with a known cap, then plug in the freq where the signal peaks on a scope or VTVM, and it gives me the inductance. Every time I find a new formula for something, I enter it into my spreadsheet. I also have a free program called "Elcad" the does a lot of the calculations, including coil turns and conversions.

Yes, what _is_ this devilry of actually finding stuff out and then applying that knowledge to obtain a predictable result? Why aren't we _all_ happy with starting our cars like Fred Flintstone?

For those interested in knowing a bit more what they're doing in addition to just doing what they already know, here's a basic how-to about determining "how many turns" for a shortwave coil when an article doesn't give you that information.

Two online calculators will get us there. First, though, for those wanting PDFs of those various RCA tube manuals, you can get them from the tubebooks.org subpage at http://tubebooks.org/tube_data.htm . The 1948 (RC15) edition of the _RCA Receiving Tube Manual_ includes an "AC Operated Shortwave Receiver" on page 220.

Now this article throws us the curve ball of specifying only a tuning capacitance (140 uuF, or 140 pF) for its tuned circuits. (This worked back when that article was published because you could go into any radio catalog--or radio store--and find ready-made RF coils specified to be used with such-and-such tuning capacitance.) But knowing that, we _can_ figure out coil specs for a first try.

So the first thing we do is assume that we have 130 pF, not 140 pF, just to make sure we've built in some leeway hitting resonance with whatever 140-pF-ish capacitance we happen to use.

And then we decide the lower end of the range we want to cover. Considering that the lowest international shortwave band with much action is the 6 MHz band. we'll make our radio start tuning right at 6 MHz.

What inductance--how many microhenries?--might that require for resonance with 130 pF? An online calculator capable of determining resonance from either angle--L or C--can help: http://toroids.info/T200-2.php . This happens to a calculator set up to find turns for a particular toroidal core, but as we use it we're also given _generic_ L and C information that will give us what we need.

So in that page we type 6 in the MHz box and 130 in the pF box, and press Calc. And we're informed that we need a 5.4-microhenry coil.

Now, assuming we don't want to use a toroidal core, we next want to know how many turns to wind on a pill bottle to get that inductance.

The calculator at http://www.crystalradio.net/cal/indcal.shtml can help us. Its "Solve for Turns" features seems to be broken, but we can use its default "Inductance" setting to do a bit of cut and try.

We leave Solve set to Turns; type 1.125 into Coil Diameter; type a trial value into Turns (let's try 10); type a Winding Length (a length equal to the coil diameter is a best practice for technical reasons, so let's try 1.125 there, too); and then click Solve.

Huh, 1.93 uH. Too little. So we bump Turns up to 20 and Solve again. Hmm, a bit over 7 uH. Hey, we can get 5.6 uH with 17 turns. That's close enough to 5.4 uH for fun, and we will certainly hit 6 MHz with 130 pF with that coil. If we want to fiddle further, we can increase the winding length a bit to bring 16 turns to exactly 5.4 uH.

That's maybe ten minutes to figure out how many turns of wire we need to hit a certain frequency with a certain capacitor and a certain coil form.

I have read a wide range of comment on this unorthodox
Kitchin design. The floating diode kinda defies physics.
However, some report good results. I deduce leakage and lucky-dip
selection of the germanium diode might explain the disparity.

I have yet to try it myself, but could be re-motivated by
postings from empirical converts ...

Hello,
Mike, AC2Q here.

Just built my 1st scratch oscilator, and while it works, and reasonably on frequency, (YES!!) there are issues I am hoping for input about.

See photos of schematic and waveform output in files section "AC2Q"

Q: Is the output distorted because it is harmonic rich, OR is it harmonic rich because it's distorted?

So is the issue more likely one requiring filtering, or is it a bias or tuned circuit issue?

Any Help Appreciated!

Mike

Topic: 27159 Message: 27160

Second one: It is harmonic rich because it's distorted. This happen, because the transistor is not amplifying a continous signal, but switching on and off. If you check the wave form on top of the coil, there it will almost look like a sine wave.
Many of that coils contain a second coupling coil, from where you can get the same nice wave form. While the amplitude is smaller, the coupling coil can drive a load.

Hello Mike

Everything is perfect. You don't need a filter nor a buffer. Just place the red output cable close to the radio's detector circuit. Sometimes it is good enough, to fix it with sticky tape on the backsite of the radio.

Bernd

I have been playing with BFOs added to older radios (late 1930s floor model with SW) James H gave me some good tips on how it was done in the S-38 and some National sets that did not have a BFO proper so I have spent the last few weeks playing with that idea in many forms. It is surprising how easy it is to do so the tip of putting the output of your osc nearby will for sure do it. Killing the AVC helps even more. And I am impressed on your build of it too. May it be the first of many osc to come from your bench.

Hi Don,
What I've done in the past if the set has the older double ended tubes is slip a piece of wire under the IF amp's grid cap and wrap a few turns around the glass tube. This wire causes feedback from the grid to the plate and make the IF oscillate, instant bfo. Tape the loose end to the the bakelite base.

Yes that would work. I tried feedback from the 6k7 grid wire to the cathode with a witch in between. It worked but I wasn't completely happy with it so I put an insulated loop around the plate pin and plugged the tube back in and put a small amount of wire over the 6k7 grid lead. that worked well and I could switch it on and off just like a real radio. (Com rec) Some of those old sets have really good performance. On that one I had the switch mounted on a bracket right at the tube and it was a big switch so parts are far enough away to stop feedback. I tried it on my Sparton 1939 set but with the switch on the front panel but too much wire so I couldn't switch it off. So I had BFO always. It works best on my GE 1935-36 set. The reason in case you are wondering was for experiments with the spy adapter set. CW was a problem so i assumed perhaps MCW was used (and it probably was then James gave me this info and I spent about two weeks with two of my old sets trying everything I could think of. As you know and obviously knew about it long before my recent discovery while it might not be perfect it certainly would allow one to operate with ease in CW mode using an old parlour set. now i wonder did any hams operate in that fashion back in the 1930s and 1940s. I think some must have as not everyone could afford a com rec or had the where with all to build a real radio (regen). Speaking of which this afternoon I plan to convert my twin 26 regen from an 80M Armstrong to a 40M Hartley based regen.

CW was a problem so i assumed perhaps MCW was used (and it probably was then James gave me this info and I spent about two weeks with two of my old sets try ing everything I could think of. As you know and obviously knew about it long before my recent discovery while it might not be perfect it certainly would allow one to operate with ease in CW mode using an old parlour set. now i wonder did any hams operate in that fashion back in the 1930s and 1940s. I think some must have as not everyone could afford a com rec or had the where with all to build a real radio (regen). Speaking of which this afternoon I plan to convert my twin 26 regen from an 80M Armstrong to a 40M Hartley based regen.

For sure! When I went to test it the 1.5v was pretty well dead although I did mange to get a squeal. I whimped out and just rewound the coil for 40M instead of changing to a Hartley. It is not one of my best sets. I had the two tubes and too much time on my hands probably. It matches my 40M TNT so I figured it should at least do 40M. I like to use the full vintage station set ups for events like the Bruce Kelly.

Topic: 27172 Message: 27172
Attachments: 1 described; binary payloads are missing from this source WARC

Well, the cabinet was rusted all over, so I cleaned and painted it, and it came out pretty good.

Inside all was grungy as it had been very wet. I replaced nearly all the resistors and capacitors, and it came to life, but not very satisfactorily. Audio seemed low, it very easily overloaded, and the notes were raspy. You have to operate with a very small coupling capacitor as there is no RF gain control.

An interesting design feature is the detector tuning capacitor floats at B+ voltage. The tuning coil has the capacitor connected across about 60% of the winding, and is bypassed at that point, and the end of the coil connects to the RF amplifier plate, giving transformer coupling. (see schematic attached) The input coil is identical, with a 500 Ohm resistor in series to load the tuned circuit to broaden response to make tuning easy, and also to reduce gain, which we don't need. I increased the detector plate load resistor, R5, from 50K to 100K which increased audio, and increased the grid leak resistor, R6, from 150K to 1 Meg with improvement. Also the 500 Ohm loading resistor on the input tank seems too high as it didn't seem to tune at all. DC on the heaters seems to be an improvement, but it's still raspy.

Seven sets of coils were available covering 430 Kc through 63 Mc, but note they are all general coverage, and the ham bands occupy only a few divisions. It has an 8:1 gear drive, which is promising, but after much futzing it still has some lost motion.

So, the saga continues. I may try making some MF coils using old IF transformers, on the other hand I think I can make a better one. (But, it's a very good looking receiver...)

If it is a 1.5 volt 01 someone hurt it when they designed it. 01s will stand anything. These are finicky. I would not use them again and could just pop the 01s in and up the voltage and be done with it but my heritage wont allow that. I must complete it. So what I did was buy a normal 6 volt lantern battery which has four 1.5 volt cells inside. I took it apart and flipped the cells and rewired it so they were all hooked parallel giving 1.5 volts with grunt. It has lasted over a year of causal listening and is just now going south. I didnt use it a lot. Perhaps once every week for 15 minutes or so. I use a bunch of 9 volts standing in a rack at the back for B power and it has worked. Just since it matches the TNT and the TNT is now on 40M (with its notorious loop modulation still installed) I felt i should put "The Twins " back in business together. Not every build has to be the ultimate. sometimes it is fun and educational to explore an idea by building it. Since it takes only a day or so of time and is fun that is how I learn. If it works to a usable level i leave it built. If a disaster I repurpose the parts. This works good enough to use so it gets to live.

Hi Don,

If anyone is interested in experimenting with BFO add-ons, we do stock some 455 KHz crystals
(hc6u format) and sockets for same, at:

http://af4k.com/hc6u_crystals.htm

Posted by: dulmagedon@... dulmagedon
Date: Sun Oct 9, 2016 5:08 am ((PDT))

I
have been playing with BFOs added to older radios (late 1930s floor model with SW) James H gave me some good tips on how it was done in the S-38 and some National sets that did not have a BFO proper so I have spent the last few weeks playing with that idea in many forms. It is surprising how easy it is to do so the tip of putting the output of your osc nearby will for sure do it. Killing the AVC helps even more. And I am impressed on your build of it too. May it be the first of many osc to come from your bench.

Maybe we need a new TV show called "Solder Wars!"

27178. Experience with Kitchin's Simple Regen Radio for Beginners

Yahoo group: regenrx (2016 — 2017)
Date: 2016-10-10 17:20:48 UTC
From: rhulett1@...
Topic: 27178 Message: 27178

I built this radio and through kindness of Rob KB3BYT tested several different diodes in the radio.

THIS is the KITCHIN schematic
http://www.learnmorsecode.com/kitchin/aK62.jpg
http://www.learnmorsecode.com/kitchin/aK62.jpg

This is the whole project:
http://www.learnmorsecode.com/kitchin/index.html
http://www.learnmorsecode.com/kitchin/index.html

The germanium diodes tested were a RS "General Purpose Germanium", D9B, unknown germanium, 2AA113, D311. All worked in the circuit. The D311 is the best, the one I got from RS is the worst. D9B, Unknown, and 2AA113 are in the middle.

The shottsky diodes tested were 1N5817, 135106, CDSH270. NONE of the Schottsky diodes receive for me.

It's strange because recall reading folks saying a 1N5817 worked nearly as well as a 1N34A. Maybe there is something wrong with my implementation. The D311 is head and shoulders the best of the batch.

Would appreciate any advice or comments.

72, Curt KB5JO

Hi Curt!
My advice is to shunt detector diode with a resistor. This will form a normal clamping circuit independent from reverse leakage current of diode which varies with temperature. The resistance is between 100k and 10Meg for different diodes, but you can estimate it with a potentiometer.

Dear amigos :

The Kitchin receiver is IMHO not exactly a regenerative detector receiver.

A circuit analysis shows a regenerative RF amplifier, coupled to a ¨floating detector diode¨...I have heard in the past that a modification is done to the detector so that the diode works into a real stable load impedance....

Wonder if any of the least members have heard about that mode. I remember seen NA5N's built solid state regenerative receiver been demostrated to me in Denver, Colorado , using a short length of wire and picking up many short wave broadcast stations with excellent quality.

Mikhail, you confirm my understanding. The explanation of why the
floating diode works must be the reverse leakage current. A high-ohm
shunt resistor can indeed stabilise performance. It is definitely
a regen, but the regen is in the RF stage, not the detector.

Has anyone experimented with an improved AF stage?
The LM386 is so noisy, so yesterday...

While i was filing paper here yesterday i came across the instruction sheets for the "TAMAR A.M. Radio Medium Wave Band"
kit circa 2005. This radio kit has disappeared like a pebble in the ocean and googling returns no results. TAMAR seems to be
only in the business of electronic diesel engine controls now.

The circuit uses a BF244B FET as regen amp. Source is via 2.2kR to ground and drain is also 2.2kR. A 2.2 nF takes from the
drain to a OA91 diode to a junction of two caps; 15 nF to ground and 100 nF to the base of the BC549C audio. There are
two more audio transistors. I mention this circuit only because it's another working example of the 'floating diode' circuit.
I may eventually post the schematic.
One oddity is the tickler winding lower end connects to the top end (= FET gate) of the tuned circuit. I wondered if that
was a misdrawn schematic but when i looked at the coil winding sketch, sure enough, that's how they did it. I still am kind
of puzzled over that. The tickler is fed thru a 140 pF variable and in the conventional circuit, the lower end would go to
ground.

I am not totally convinced of the 'reverse leakage' theory.
The TAMAR kit has capacitors before and after the diode. These are non-lytic type caps and DC resistance
thru them is infinitesimal. Even with a Schottky with a resistor across it, in this circuit, there is NO DC
discharge path.
Has someone actually used the Schottky with parallel resistor, and found that worked equivalently to a,
say, OA91 ?

Hi Arnie!
The all six regen circuits in 1913 patent of Armstrong contain also as demodulator „floating clampers“ - there is no grid leak resistor. This is stupid - SPICE will refuse to simulate it.
http://www.pavekmuseum.org/Armstrong/1113149.html
http://www.pavekmuseum.org/Armstrong/1113149.html
The design of an electronic signal processing network should start with a block diagram. Despite the ocean of information about regen circuits in the Web, I can’t find block diagram of regenerative network. The regen network should be reinvented.

The first paragraph of Circuit Description (and the schematic itself) confirms it is a regenerative RF amplifier, the "floating diode" being the detector. Building this radio was mainly my exercise to participate in project for another group. I'm not all that happy with the radio's performance, it is too sensitive to stray capacitance. Thankfully didn't invest a lot of time and money in building it, guess I got my money's worth lol.

FWIW, the best Regen I own is the Bayou Jumper built using a PCB from N5IB, evidently based on an N1TEV design. It is solid as a rock and I have easily made QSOs on 40M with it paired with a "2Fer" 2W transmitter. Even had a 2xSpy QSO with N5IB. Of course it is much more complex than the "Simple Regen".

No – there’s no joke about the QSL, despite the date.
I omitted one line,
“4 ‘Sevens’ that day. Hope cuagn next spring”.
I believe he is reporting reception only, while working someone else.
Because of scarcity of tube rectifiers and nonexistence of electrolytic filter capacitors for high voltage,
most (?) ham transmitters of the time, if not powered by a motor-generator DC supply, used “raw A.C.”
on the transmitter. But the “sync” i do not understand, among a couple other points.
-Hue

Hmm, look at the date, it might give you some clue (only maybe).

"April 1^st ’28 at _abt 0200 G.M.T."

Another kicker, the term "73's" was a child of the '70s CB craze, an
incorrect use of 73. . . To say 73's would be like saying "best
regards's" .

and readily found by searching.

THIS is the KITCHIN schematic
http://www.learnmorsecode.com/kitchin/aK62.jpg

This is the whole project:
http://www.learnmorsecode.com/kitchin/index.html

This Kitchin design is innovative and worthy
of emulation and experimentation. It has been
widely discussed, not least because of the
"floating diode" innovation, an anomaly of
semiconductor physics, in this implementation
best explained by leakage current.

Discuss!

Michael

The ‘Bayou Jumper’ may be in the group files, but i usually find it easier to just look on the overall net, so i googled
and found it on a French site,
http://n5ib.net/Sauteur%20de%20Bayou%20Overview.pdf

I see it dispenses with the diode detector and has the FET as regen detector.
The hand capacity with your Kitchin circuit is due to the particular construction, isn’t it?

Michael, i also was going to post that the ‘floating diode’ was a particularity of semiconductor diodes
BUT i suddenly recalled i had seen the same circuit, using a vacuum tube diode, in some schematic
of a gen-coverage SW radio – all i can recall is it wasn’t a major name company – and wasn’t a top
end type receiver – but i can’t recall for the life of me which receiver, although i’ll no doubt come
across it again, as i’m sure it’s somewhere in my collection of dozens of receiver manuals.
Darn, this is bugging me now. I wonder if i can dig thru my manuals without the nagging feeling i
should be doing something more important right now....

The ‘diode leakage’ theory has to demonstrate a DC leakage path. With a low value capacitor in series, can you show
me a DC path? I have tried the circuit with a capacitor in the 100s of pF – there is NO dc leakage thru such a cap.

** The all six regen circuits in 1913 patent of Armstrong contain also as demodulator „floating clampers“
** there is no grid leak resistor

That old tubes haven't been evacuated properly. So instead of a resistor the rest of atmosphere inside the tube caused the leak. For a short time periode they have sold extra detector tubes and amplifier tubes, where the latter ones had a better vacuum.

I tried resistors above schottky diodes in every direction and above the capacitor. Nothing worked as well as a germanium diode. The worst germanium diode worked better than the best schottky. IMO it has something to do with either the recovery time or another unknown behaviour. Any resistor combined with the diode would reduce the Q of the tank circuit.

To avoid this circuit, an infinite impedance detector like this would be a good replacement:

More about easy to ¨get going¨ regenerative radios !

Published by Technical Topics column of Radio Communications British Magazine... the circuit that has proven to me easier to ¨get going¨ seems to have originated in Holland, and it had a funny name like ¨ Rotor¨ or something like that.

Essentially it uses a cascode regenerative detector with the classic ECC81/12AT7/Russian 6N? 1 , 2 or 3... The circuit is completed with another identical tube for the audio... BUT, it you want real loudspeaker volume... add a ECL82 / 6BM8 and you will enjoy nice audio by adding some feedback from the audio output transformer...

One additional benefit of the circuit is that it was published with precise data to wind coils for easy tuning bandspread on the amateur bands.

My good amigo Bernardo CO3BN built one and was amazed by the performance he was able to achieve, even when just using the second half of the audio tube coupled to the output transformer.

Bernardo is helping newcomers to amateur radio that have obtained the beginners license and are presently only on 2 meters, to listen for the first time on 40 meters, where one can pick up many Cuban stations during the daytime hours, and a lot of DX at night. The RF attenuator is just a potentiometer... and the bandspread is excellent for tuning for CW and SSB stations.

73 and DX

Arnie Coro

CO2KK

BTW... I insist ... so far not one of the many solid state regenerative receivers has matched even rather simple sets built with tubes !!!

Another thing I have tried (successfully) is a very small amount of forward bias with a 1N5711 or similar Schottky diode, something like 1 megohm in series with a 1.5 volt battery, to "help" overcome the diode barrier. Solves essentially all the problems caused by the unobtainium factor involving 1N34 and similar diodes. The battery will last essentially forever (or at least shelf life) since the draw is down in the one or two micro-ampere range. Just look for a suitable place to insert the battery and series resistor, and if you have the tools, adjust the size of the resistor until a just barely measurable forward current flows.

Try connecting the battery and bias resistor in series with the "cold" end of the tuned circuit, and also bypassing the cold end of the tuning circuit to ground with a .01 uFd disk ceramic cap. The purpose of this last is to bypass RF around the bias circuit. Obviously there needs to be a completed circuit of some sort involved - a totally open path will not perform properly. Ideally, you will be able to fiddle with things until you reach the optimum sensitivity point, theoretically even better than a "red hot" germanium point contact detector. Select the value of the series resistor for best results. As in pretty much all cases where this sort of magical mumbo-jumbo is involved, experimentation is everything.

Interesting that this one performs better than the original Kitchin circuit. I don’t at the moment understand the why of this.
I noticed this circuit has a reverse-bias clamp diode across the gate circuit. I presume this will only come into effect in oscillating state,
and i wonder if there’s any benefit. I think the diode here in an oscillator circuit by disallowing positive-bias gate current, only decreases
the harmonic content in the generated RF.

It's possible for the diode + capacitor in that circuit to conduct on peaks, acting as an integrator to keep the capacitor charged as its charge leaks away. A leakage path to discharge the diode would be through the diode's back resistance--a high resistance to be sure, but a finite resistance nonetheless--and ultimately its driving circuitry and the internals of the LM386.

Two more floating-diode circuits: By Goodman's cathode-to-cathode two-diode product detector of the 1960s (was claimed to have) used the back resistance of one of its diodes as a dc return. Lew McCoy's Mighty Midget receiver (April 1966 QST) originally used a voltage-doubling detector that allowed one of its diodes to float exactly in the manner of the Kitchin Receiver; a later Feedback or Technical Correspondence item--not indexed so far as I can tell, and I'm unwilling to go issue by issue to find it--corrected the gaffe and refactored the iffy two-diode detector into a half-wave (single-diode) circuit that included a well-characterized load resistance. The distillation of the Mighty Midget coverage for a later ARRL Handbook or three (1969, at least) includes the half-wave detector.

Although I'm glad that those who have built the Kitchin circuit and found the results gratifying have had, and maybe are still having, fun, had I been on the QST technical staff when that article was submitted for editorial review I would have recommended that it not be published on the grounds that the function and operation of the floating diode (a) was not sufficiently explained by the author and (b) would therefore cause needless technical controversy to the net effect of calling into some question the savvy of QST's technical staff.

That over a decade later hand-wringing continues about the the function of the diode proves my points.
Readily reproducible regenerative detector circuits abound that work explainably well without such hand-waving. I recommend such circuits over the less well-defined and -understood.

Please define low temperatures.
My current interest in triac control is to be used in table top PCB
toner transfer projects
using a laminator or a hot plate.
Pretty much indoor living space..kitchen temperature... 65 F to 75 F
degrees.

Dreaming up other triac circuits.... basement flood pump... attic
exhaust fan....
there really is no temperature below 38 degrees....
but
I saw an outdoor walkway lighting triac circuit that COULD be exposed to
winter
freezing temperatures..... so then I thought a 5 watt ceramic wire wound
resistor
could be used to keep the circuit humming.

I asked how you (indefinite pronoun) using the diode leakage theory, explain the working of the “TAMAR regenerative radio kit”, which used capacitors
both before and after the diode. (I personally think the circuit does not require two caps in this circuit, and one could be removed with no loss of function.)
If i find the schematic i mentioned, a vacuum tube ‘floating diode’ in a commercially sold receiver, will that put to rest the semiconductor diode theory?
That might be enough reward for me to go looking for it.

I’m thinking i see it this way: The DC level the diode output circuit depends on the load capacitance and resistance. If this combination of load values is such
that the driven stage input capacitance drains below peak before the next train of modulated RF pulses, the diode will never be back-biased by the load
capacitor to nonconduct. Or you could maybe say the R and C values never allowed the modulated pulses to be integrated. Diode current always flows
during the ‘conduct cycle’. You depend on the load R to drain the load C. C discharge path does not require a backward path thru the diode. (For good
reason this circuit is NOT used in rectifier circuits to deliver serious power.) If i’m right, relatively low load capacitance (to ground) and low load resistance
(to ground) => favors the floating diode circuit.
I have in this circuit used a large range of capacitors, all non-lytic types in the pF and nF range, and all worked with
hardly any detectable difference. It does not faze me in the least or dissuade me that it’s not well understood as long as it’s reproducible, which means it’s
not just a fluke from using some problem circuit components.
I could be all wrong.....
This discussion has me itching to get out the breadboard again.

See, that's the thing that always bugged me about the floating diode circuit -- for me, it was not reproducible, by which I mean that I used the floating diode in a number of different BJT regen circuits, and sometimes it worked, sometimes it didn't. When it didn't work, I got either poor sensitivity or hysteresis in the regeneration control, making it impossible to set the regen right on the edge of oscillation; inclusion of the diode would cause the circuit to slowly creep up closer and closer to oscillation (over a few seconds) until it snapped over and required the regen control to be reduced significantly to bring it back down below threshold.

So if you're going to experiment, I think it would be useful to see in which specific circuits it works well, and in which specific circuits it does not work well. I wrote up my very preliminary findings on this subject here:
http://theradioboard.com/rb/viewtopic.php?t=5790
http://theradioboard.com/rb/viewtopic.php?t=5790.

Personally, I've given up on the floating diode because I like to experiment with unusual BJT oscillator configurations and I cannot predict in advance if the floating diode will work well or not. I just take the AF off of the emitter and add some more AF amplification.

No. I looked at it somewhat simplistically. There are effectively 2 capacitors in series with the diode. The actual series (“float”)
capacitor and the load-to-ground capacitance.

1. On charge cycle, these divide the peak DC value between them, according to their relative values.

2. As long as the driven stage input capacitance is allowed, by its parallel resistance, to discharge (drain down) into the load resistance, this one
capacitor will discharge, on the non-conduct, resting cycle, down from its peak.

3. So – on next conduct cycle the sum “back bias” of the TWO capacitors is now less than the instant peak input voltage.

4. Diode current will again flow, charging them again.

You can see that the circuit depends for good effectiveness on the load capacitance being not a great deal larger than the float
capacitor, and the load resistance i would think needs to be in the “sweet ballpark”, high enough to allow the input capacitance to
charge to as high as possible compared to the float capacitor, but low enough to be able to drain this cap on the non-conduct cycle.
I wonder if people have had not good results with this circuit, and if so, maybe because it looks (to me) like the values of these 3
components have to be all fitted into a smaller ballpark. (I mean there’s less tolerance, so you can’t assume it automagically will work?)
So yes, maybe it is less ‘reproducible’ as others suggest. And so, less desirable. It only – i think – offers a cheap & dirty way to couple the
RF stage to the detector to the audio without transformer coupling.
As for the hysteresis issue, just mentioned, i’m stumped. I’ll have to puzzle over that.

This is just my little more careful look at what i previously posted. This analysis still does NOT depend on any DC discharge path
thru the diode.

Your mention of taking the audio off the emitter brought to mind a couple of instances i'd seen.
R. A. Penfold in the second of his small Babani (publisher, U.K.) books on simple regen circuits,
touted this approach (using a JFET) for its better large-signal handling capability than the drain-
output circuits.
The second circuit i remembered (some of you have seen this too) is in a 1954 'Radio News'
project article that showed a submini tube driving a single transistor. The audio was extracted from the regen detector by a resistor in the cathode leg, so as to be able to drive
the input impedance of the transistor. The tube B+ was something like 7.5 volts. The transistor
may have even been direct coupled to this output resistor; i don't recall, but i have seen a
couple of 1950s radio-control superregen circuits where the tube plate current went right into the transistor base-emitter junction. (I can see that might cause complications, but part
of why it could work was maybe that those transistors were much lower – beta (current gain)
than now.

One thing I should mention that I did not consider was the quality of the capacitor used after the floating diode. In my experiments I just used some junkbox 10 nF capacitor. However, it's perhaps conceivable that this capacitor should be a low-loss, RF-grade capacitor.

The title of Charles Kitchin's article was "A Simple Regen Radio for Beginners", "Need a simple, fun project - possibly for a Scout Radio Merit Badge?" (QST Sept 20000, p62ff) - available as a pdf online. The "floating diode" design provides an interesting challenge for experimenters willing to tinker with germanium diodes, layout, components etc. NA5N replicated it in the Pipsqueak and RATT-3. But as Dave explains with clarity, it is somewhat contentious and probably not suitable as a Scout Radio!

Rob, with reference to another circuit, you ask "What is the source of this image?" It is another design by Charles Kitchin, easily found online - reliably reproducible. For your purpose, I would however recommend a clone of the MFJ-8100, which is sure-fire and fairly simple. A number of basic variants are readily available online.

Michael

You can take audio off many places. During a frey when people were worried about having HV in the headphones I surmised the headphones are only sensing changes in load and so hooked them in the B neg circuit instead. Worked perfectly. Sometimes the esoteric descriptions of how things including regens work are pure balderdash. It is really not that complicated. Tube Regens? For sure. I say it takes 100 transistors to equal one good tube.I know that is an overstatement but it makes the point. I build the solid state ones sometimes just to keep current. but real radios do glow in the dark. At least here at VE3LYX

Below freezing. Check you data sheet for current required to turn on the triac at the low temperature. I know many engineers who do not read that spec. One lost his job when all the Canadian products failed in the winter.

It is just a good idea to design your projects for the proper use at all temperatures. SCRs and Triacs have that low temperature problem.

Subject: [regenrx] moc3020 triac driver.....triac has a lot less sensitivity at low temperatures

Please define low temperatures.
My current interest in triac control is to be used in table top PCB toner transfer projects using a laminator or a hot plate.
Pretty much indoor living space..kitchen temperature... 65 F to 75 F degrees.

Dreaming up other triac circuits.... basement flood pump... attic exhaust fan....
there really is no temperature below 38 degrees....
but
I saw an outdoor walkway lighting triac circuit that COULD be exposed to winter freezing temperatures..... so then I thought a 5 watt ceramic wire wound resistor could be used to keep the circuit humming.

Thanks for your input. I find it always worthwhile to hear about other's experiences and conclusions.
Hysteresis: i tentatively suggest – the diode below the 'knee voltage', has a variable resistance inverse to the source voltage. Enough that the forward resistance for very low

source voltage may be like 10k or even 20k (i don't remember exactly; it's been decades since i graphed that.)

When you back off the regen control, the RF voltage to the diode decreases => the series resistance of the diode (in the conduct cycle) increases => loading on the regen amp

stage decreases overall => this tends to counteract your decreasing the amplification of the regen stage.

As for the long (seconds) buildup to rollover, now that IS interesting. Obviously something has a long time constant, and i think it must be in the R and C post-diode.

It even occurred to me (maybe irrationally) that instead it might even be a junction heating effect in the diode. That might account for the long (relative) time up to the

rollover point.

The 'floating diode' circuit in this regen came into being because apparently Mr. Kitchin felt the FET would not so efficiently function as a detector, but that seems not to be

the case, as plenty of others have proven great results without bothering with a post-amp detector.

With a MOSFET RF amp, it won't detect (rectify RF) so you must go to a post-amplifier diode (or other detector).

I think Penfold's book showed a simple MOSFET receiver like this. I seem to recall a QST magazine project of a MOSFET dip-meter where the author said he was surprised to

be able to pick up international broadcasting on this homebrew test set.

I noticed in this QST article of the Kitchin beginner’s circuit that there are special precautions taken with the placing of the diode-capacitor-resistor

series network. That maybe is a hint something not so good might happen in a freestyle homebuild. As in “might get squirrely”. Maybe not so

‘reproducible’. I think the series 22k resistor is to “de-reactive” the network. I wonder if it would be well to do the RF filtering before the resistor

instead of after it. Also i think maybe i’d try moving C5, the LM386 input capacitor, to the top of the volume pot. I note that C4, the diode series cap,

is 5x larger than C5, across the LM386 input. This is the kind of proportion you have to maintain to get best audio level out of the diode. I think.

For our overseas readers, “squirrel” is a small tree living rodent, with very sudden jumpy movements. So in electronics, it means “liable to be unstable”

-Hue

>Hello Curt

Are you building this circuit?

http://www.arrl.org/files/file/Technology/tis/info/pdf/0009061.pdf

Then make sure to use a genuine Germanium diode. Others are not working well in this kind of floating detector.

Best regard, Bernd

This is a pertinenet observation, Hue.

The Pipsqueak version has some noteworthy modifications.
I think we discussed this many moons ago.

Here the Kitchen values and in brackets those of a Pipsqueak mod :-

R1+R2 1k+100k (200k), R3 1k (100k). R3 as 100k has been reported
as improving regen control. Kitchen follows the 1N34A and 0.01uF
directly with the AF pot and the LM386. The Pipsqueak inserts a
2N222 before the AF pot. Kitchen emphasises the importance of
layout around the 1N34A, as you note. This and the 100k R3 are probably
significant. It would be interesting hear of any exact
replication of Kitchin's design - and of the Pipsqueak mod.

KR1S has some information on his experience homebrewing a similar set to the MFJ 8100:
http://theradioboard.com/rb/viewtopic.php?p=33299#p33299
http://theradioboard.com/rb/viewtopic.php?p=33299#p33299 .

There's also some information here:
http://zpostbox.ru/regenerative_receiver_the_last_of_the_mohicans.html
http://zpostbox.ru/regenerative_receiver_the_last_of_the_mohicans.html .

I've not built it myself, but everything I've read (from people who have built it)
indicates that is a reproducible and well-performing circuit.

Best regards,

It occurred to me also, in the ideal regen, you want as little "stuff" hanging off the tuned circuit.
In "A Simple Regn Receiver for Beginners"
http://www.arrl.org/files/file/Technology/tis/info/pdf/0009061.pdf

you have a diode and a load of something less than 120kR on the tuned circuit. The diode has
a variable capacitance when not conducting and a variable resistance when conducting, both varying with the voltage applied. I can see how that might complicate the operation of the regen
control. The circuit IS simple and so it IS reproducible by the homebuilder, but i can see how you
might have problems with the floating diode, floating off the tuned circuit, that is. An FET buffer
between the regenerative amp and the diode would maybe offer more "reproduciblity" with the floating diode and probably more gain than the same FET alone in an infinite-impedance detector,
but it doesn't have the virtue of absolute simplicity.
However, saying that, i suddenly remembered the 2 transistor (FET + bipolar) circuit published
here some time back, which gave wonderful sensitivity, with a minimum of parts.

Hue, your link is, of course, to the original Kitchin design
we have been discussing, and which is known to be temperamental :-)

It is not always easy to find corroboration from enough different
reviewers on each of the many interesting-looking circuits found
on the web. Perhaps group members have suggestions. If a few designs
were recommended by many, that would be very useful!

The MRJ/TenTec is however fairly easy to reproduce and is well reviewed.

I bought an MFJ8100 at a hamfest 18 years ago for $80.
I took that radio with me whenever I traveled and had to overnight stay
in hotels.
I dropped a magnet wire out a window and listened to the world.
One night I heard CW 5 letter groups and I wrote out all the letters.
Not a single word was spelled on the paper. At the very end of the
transmission a woman's voice said
"thank you gentlemen".
I took that radio to Disney World to kill time in the evenings when the
grandchildren were sleeping.
I was stunned at the number of stations piled on top of each other from
all over the world.

I lent that radio out a bunch of times to beginner hams.... it always
was returned when they bought their own radios.
Then I lent it to my daughter for her kids.... I'll never see it again.

So as we are building radios I am always looking for THE ONE, THE BEST
ONE, that IS repeatable
and other builders can recommend.
And hearing the MFJ8100 IS such a circuit... I'm very interested.

Many apologies but what I thought would be simple and straightforward has turned into a rat's nest. All I was interested in doing was building two regen receivers manhattan style. One "simple" (I mistakenly thought "simple" in the name of an article would mean "simple"), one "complex". Have built the first and got all the fun out of it needed.

Now, attempting to move on the the "complex", I read about MFJ8100, Ten Tec, a "High Performance Regen", Desert Ratt 2 (and 3), one FET / one bipolar, etc...

Planning to build a 716 resonator radio basis at least two people who have had success. What is surprising is the plethora of variations on a century-old concept, many of which evidently work sometimes for some builders if components no longer readily available are used. When I look at the simple superhet or DC receiver, most are using a standard design. If wired correctly they will all work every time. I built a W7EL transceiver with cheap discrete components manhattan style and it worked beautifully from the beginning.

Is there a standard, bulletproof, stable, operable Regen design that can be replicated using readily available inexpensive modern components? It's strange to contemplate farmers in the 30's building radios to listen to AM broadcast with a few cheap parts.

Curt

for simple, consider doing a homebrew version of the Ozark Patrol. It will workokay using any common npn for its 3 transistors. Only exotic parts are a variable cap and an audio transformer. It works amazing, using both audio and rf feedback it has agc like behavior against qsb.

For complex, consider the WBR. A more complex coil and a couple varactors gives a good cw receiver across one ham band.

my homebrew new 3 transistor transmitter should be skcc qrv one if these days, which reminds me, visit N5IB website for another candidate solid state regen.

Not so strange as un-useful. The "few cheap parts" that built a regen in the 1930s--and the audio transducer used with it--are quite different in 2016. The active device(s) available for the detector generally have much higher gain, including much higher gain at VHF, than the vacuum tubes of that time, and must be operated at generally much lower voltage. This makes them more efficient energywise, but easier to overload in a signal-handling sense and more prone to parasitic oscillations in an operational sense.

A one-triode audio amplifier driven by a triode detector could easily drive yesterday's high-impedance magnetic headphones to quite satisfactory volume, especially on reasonably strong AM broadcast signals. Without undertaking a significant investigative/design effort, you won't be able to duplicate this with two transistors, and maybe not at all. With a transistor detector followed by an integrated-circuit audio amplifier, yes, but this approach gives on other concerns.

IC audio amplifiers--especially ICs like the LM386 configured for maximum gain--driving today's low-impedance speakers, headphones, and earbuds are _deceptively_ simple, Without forethought and care given to proper delivery and routing of input signal, output signal, and power, they can quite easily oscillate at AF or RF, sometimes only on signal peaks, especially low-audio-frequency power peaks. (ICs of the LM386's general design can also generate RF hiss that required careful circuit-board layout and parasitic-oscillation suppression [that RC network to common across the device output] if they are not to compromise LW and MW reception.)

The first step in getting good, repeatable regen performance with minimal modern parts is to recognize that "simple" in 2016 is more complicated, and requires greater design and implementation care, than "simple" of 1936.

Best regards,

Dave

Yes; it's tempting to think of "few transistors" as being equivalent to "simple design", but for regenerative receivers often the opposite is true, considering the complex dynamic behaviour of a single-transistor regenerative detector and all the ways it can misbehave. And sometimes low-transistor-count designs use reflexing, making the system even more complex and prone to misbehaviour. I personally do tend to favor low-transistor-count designs (having built and designed several), but I am careful not to fool myself into thinking that all such designs are "simple" or even readily reproducible. (The perennial and recently revived discussion surrounding the "simple regen" with the floating diode detector being one good example.)

One of my projects (progressing at a snail's pace) is building an old-fashioned, 6- or 7-transistor non-regenerative superhet. I used to look at all those transistors and think, "how complex!" But now, my reaction is in fact the opposite -- I see all those stable and fixed-frequency gain stages, the set-and-forget IF transformers, all capped off with a simple (and non-floating!) diode detector, and think, "what a simple, elegant design!"

> Dave

> amateur radio W9BRD

P.S. Dave -- still hoping http://dpnwritings.nfshost.com/ej/regenerative_receiver/ http://dpnwritings.nfshost.com/ej/regenerative_receiver/ will be updated someday!

Topic: 27229 Message: 27236

Building a higher performance regenerative receiver means separating detection and Q-Multiplying into two distinct stages with only the tank coil in common. Each stage is optimized for its purpose. For example the Junkbox Regen at https://circuitsalad.com/2014/12/06/another-excellent-performing-regen-circuit-coming-shortly/ https://circuitsalad.com/2014/12/06/another-excellent-performing-regen-circuit-coming-shortly/ and https://circuitsalad.com/2015/01/22/variation-on-junk-box-bipolar-regenerative-receiver/ https://circuitsalad.com/2015/01/22/variation-on-junk-box-bipolar-regenerative-receiver/

Putting regeneration and detecting into one single BJT regenerative stage is asking for a poor performance.

I wouldn't use any floating diode as a detector in a regenerative receiver. Best practice is to use a BJT detector in stead which is connected onto the tap of the tank coil, the same tap on which the feedback capacitor C2 of 1 nF is connected from the emitter of the Q-Multiplier Q1.

Or use a Darlington pair as a detector in combination with a differential pair type Q-Multiplier. Advantage of this circuit that coil taps or links coils are not needed anymore, which makes band switching much more convenient.

27238. Pentode Transconductance and Gain

Yahoo group: regenrx (2016 — 2017)
Date: 2016-10-14 23:24:33 UTC
From: J Ed
Topic: 27238 Message: 27238

Consider the 12CN5 tube. At 12.6v plate and screen, it has 3800 micromhos of transconductance and 40K plate resistance. Assume I want to use it as an RF amplifier ahead of a regenerative detector. Is there a decent way for me to translate those numbers into useful gain?

If it helps, assume my plate load is a 100 uH inductor and the frequency range is 3.45 to 4.05 MHz. These are all consideration points for a receiver I may want to build.

I gather you want to know a gain _number_ for your potential stage. That will depend on many things, beginning with the degree of voltage step-up at the 12CN5 grid, and whether or not you tune the tube's plate to resonance or just use that 100-uH choke as a reasonably high impedance across which to develop output. It's hard to figure.

But consider the following, please. You're talking about operating your regen at 80 meters. Especially assuming that you'll want to use your transmitting antenna for receiving, a regen at that frequency will need loss, not gain, between its detector and the antenna system to maximize use of the receiver's restricted dynamic range. (Another way of saying this is the detector's noise floor will be much lower than the antenna system noise floor, and additional gain ahead of the detector will only worsen that relationship, making stronger signals overload the detector "sooner.") So what I recommend you first try instead is the following:

Configure your 12CN5 as a grounded-grid amplifier. Those 12-V-on-plate-and-screen tubes were generally designed to operate with their cathodes grounded for dc and their grids above dc ground through a high-value resistor--specs for the 12CN5 say 2.2 megs--to let "contact potential" bias do its thing. So connect a 2.2-meg resistor between Grid 1 and common, and then bypass the grid to common with 0.001 to 0.01 uF.

To use the tube's cathode as the RF input, connect between cathode and common an RF choke of a value high enough to provide a reactance of 3 k or more at 80 m, and then ac-couple your antenna system to the cathode via a 0.1-uF ceramic cap.

Assuming the tube biased to exhibit Gm of 3.8 mS (as the 12CN5 spec sheets show), the input impedance of the cathode will be 1/0.0038, or 263 ohms. That's equates to an 4.x-ish SWR relative to 50 ohms, but even with the low gain of the 12CN5 operating in grounded grid, your receiver will still be far too sensitive at 80 m to make full use of the detector's limited dynamic range, so the mismatch loss between your antenna system's 50 ohms and the cathode's 263 ohms will only act to your advantage.

What you want to do now is _add resistive attenuation_ between antenna and cathode to bring the antenna-system noise floor down to a level _just noticeably higher_ than your detector noise floor. You will probably end up with 15 to 20 dB of added attenuation, maybe even a bit more, between the antenna system and the 12CN5 cathode.

Between the I/O isolation afforded by the GG stage--although coupling between the 12CN5's hardwired-to-cathode Grid 3 and plate will offset this isolation a bit--and the further isolation afforded by 15 to 20 dB of additional attenuation, your detector will be nicely isolated from the antenna.

BTW, the foregoing assumes very light coupling between the RF amp plate and detector tank. I recommend 10 pF at 160 m, 5 pF at 80 m, and so on.

The page http://dpnwritings.nfshost.com/ej/wr/ http://dpnwritings.nfshost.com/ej/wr/ shows my implementation of this approach at 40 meters. The result is a very good CW/SSB receiver that doesn't frequency-pull on strong signals before my ears send me reaching for the AF GAIN control (or an RF attenuation pot if I had one installed).

Best regards,

Dave

The detector attributed to Gi3XZM is such a one:
http://www.qsl.net/va3iul/Homebrew_RF_Circuit_Design_Ideas/80m-20m_Regen_RX_GI3XZM.gif
http://www.qsl.net/va3iul/Homebrew_RF_Circuit_Design_Ideas/80m-20m_Regen_RX_GI3XZM.gif

That circuit first appeared in the RSGB _Radio Communication_ column "Technical Topics," edited by the incomparable Pat Hawker, G3VA.

2N3904s, 2N2222s or other standard small-signal BJTs will do for the BC109s. Likewise MPF102s, 2N3819s, 2N4416s and more for the JFET.

Still have yet to try one of these. I believe that our own Les Smith has been greatly enjoying a GI3XZM detector at 80 meters Down Under...

27242. Thread for success?

Yahoo group: regenrx (2016 — 2017)
Date: 2016-10-15 11:03:49 UTC
From: rhulett1@...
Topic: 27242 Message: 27242

It seems a common thread for simple stable reproducible circuit is RF Amp, Regenerative detector, AF amp per N1TEV's "High Performance Receiver Design" Nov/Dec 1998 QEX.

Use a bipolar transistor for RF amp, JFET regenerative detector, IC or transistors for AF amp. The Bayou Jumper, GI3XZM, Junk Box special, High Performance SW Receiver are all based on this with a variable capacitance (diodes) used to adjust the regeneration and tune the radio. Using a Bipolar regen stage (like DR2) works better for AM. Seems variety of JFETs work, about any cheap Bipolar will work, nearly any diode will work.

Any other circuit variations like floating diodes and resonators may or may not work depending on unknown factors like components used, circuit construction, whether o'scope is attached, moon phase, etc?

> I gather you want to know a gain _number_ for your potential stage. That will depend on many things, beginning with the degree of voltage step-up at the 12CN5 grid, and whether or not you tune the tube's plate to resonance or just use that 100-uH choke as a reasonably high impedance across which to develop output. It's hard to figure.

I'm not looking for a quick answer. From reading your entire email, I think you have given me exactly the information I sought, or at least an excellent way of thinking about it. The goal is to understand the mechanics behind the circuit, not just find a circuit that will solve my problem.

> But consider the following, please. You're talking about operating your regen at 80 meters. Especially assuming that you'll want to use your transmitting antenna for receiving, a regen at that frequency will need loss, not gain, between its detector and the antenna system to maximize use of the receiver's restricted dynamic range. (Another way of saying this is the detector's noise floor will be much lower than the antenna system noise floor, and additional gain ahead of the detector will only worsen that relationship, making stronger signals overload the detector "sooner.") So what I recommend you first try instead is the following:

You're right - I may throw up a wire for testing the rig, but I'll likely use a sort of dipole or other wire antenna for use. I have used regens in the past but have mainly used them for AM BCB. Trying to get them to work better for shortwave is a goal I have.

> Configure your 12CN5 as a grounded-grid amplifier. Those 12-V-on-plate-and-screen tubes were generally designed to operate with their cathodes grounded for dc and their grids above dc ground through a high-value resistor--specs for the 12CN5 say 2.2 megs--to let "contact potential" bias do its thing. So connect a 2.2-meg resistor between Grid 1 and common, and then bypass the grid to common with 0.001 to 0.01 uF.

Interesting. I haven't used one as a grounded grid amplifier yet.

> To use the tube's cathode as the RF input, connect between cathode and common an RF choke of a value high enough to provide a reactance of 3 k or more at 80 m, and then ac-couple your antenna system to the cathode via a 0.1-uF ceramic cap.

So a 150 uH choke would work well for 80m. I could use one of those molded chokes or I could use a bunch of turns on a ferrite toroid core.

> Assuming the tube biased to exhibit Gm of 3.8 mS (as the 12CN5 spec sheets show), the input impedance of the cathode will be 1/0.0038, or 263 ohms. That's equates to an 4.x-ish SWR relative to 50 ohms, but even with the low gain of the 12CN5 operating in grounded grid, your receiver will

still be far too sensitive at 80 m to make full use of the detector's limited dynamic range, so the mismatch loss between your antenna system's 50 ohms and the cathode's 263 ohms will only act to your advantage.
> What you want to do now is _add resistive attenuation_ between antenna and cathode to bring the antenna-system noise floor down to a level _just noticeably higher_ than your detector noise floor. You will probably end up with 15 to 20 dB of added attenuation, maybe even a bit more, between the antenna system and the 12CN5 cathode.

I think I get it.

> Between the I/O isolation afforded by the GG stage--although coupling between the 12CN5's hardwired-to-cathode Grid 3 and plate will offset this isolation a bit--and the further isolation afforded by 15 to 20 dB of additional attenuation, your detector will be nicely isolated from the antenna.

So the signal levels from a good outside antenna need to be reduced to avoid overloading the regenerative detector. In all of the AM regens I've built, I've never had to do this and I never noticed any problems. What is different here?

> BTW, the foregoing assumes very light coupling between the RF amp plate and detector tank. I recommend 10 pF at 160 m, 5 pF at 80 m, and so on.

I'm guessing this is the same reason people use a tiny trimmer when building a regen where the detector is first.

> The page http://dpnwritings.nfshost.com/ej/wr/ shows my implementation of this approach at 40 meters. The result is a very good CW/SSB receiver that doesn't frequency-pull on strong signals before my ears send me reaching for the AF GAIN control (or an RF attenuation pot if I had one installed).
> Best regards,
> Dave
> amateur radio W9BRD

When using the 12CN5 as the detector itself, I've noticed that it will readily oscillate where other tubes didn't cooperate. If I used it as a straight detector, I assume I'd still need to use an attenuator ahead of the tuning tank? I've also considered having two tanks; one would be coupled to the plate circuit with a tickler winding and the other would be coupled to the antenna. The coils would be inductively coupled like an IF transformer, or one of Dave Schmarder's designs where the pancake coils are aimed at one another.

This is all very good information. Thanks for taking the time to respond.

** So the signal levels from a good outside antenna need to be reduced to avoid overloading
** the regenerative detector. In all of the AM regens I've built, I've never had to do this
and
** I never noticed any problems. What is different here?

A detector reaches it's best sensitivity for AM, if either the regeneration is just at the point or a tiny little bit into oscillation. Then it beaves a little bit like a synchron detector. When oscillating, the detector tends to lock into a strong signal. This behaviour is an advantage, when receiving AM signals, otherwise often you would hear a heterodyne tone.

When receiving SSB, the detector has to oscillate at one particular frequency ~1.5kHz away from the center of that receiving signal, to act as a BFO. Low frequencies of a voice are only 200-300Hz away from the detector frequency and sometimes they are strong, so the detector is tending, to lock into them. Now the detector is overloded.

To avoid/improve overloading:
- reduce the coupling between preamp and tank circuit
- build a tank circuit with a low impedanc (low L, high C values)
- turn the regeneration into a stronger oscillation
- when receiving CW, turn the detector frequency to a higher tone >= 1kHz
- use an rf attenuator and turn the signal down to just above the noise level.
- shielding the tank circuit, to avoid direct reception
Being able, to change the amplification of the preamp from +6dB to -40dB, would be perfect.

Best regards,
Bernd

RF signal attenuator

Certainly a most useful, I should say an essential part of a well designed regenerative receiver, is the signal attenuator between the antenna and the radio's input...

A step attenuator designed to work into a 50 ohms input impedance with steps of 0 dB, minus 3dB, minus 6 dB, minus 10 dB... then jump to minus 20 and minus 30 dB....

This will give you a very nice range of attenuation that helps to make the receiver behave better. That home built resistive attenuator with switches used ahead of a a good quality superheterodyne receiver will transform that radio into a very useful test instrument !!!

Using a dual tuned bandpass input filter after the resistive step by step RF attenuator will give the receiver very nice handling properties , turning it into a useful test instrument too.

A REGENERODYNE receiver using a well designed front end bandpass input filter and signal attenuator working into a variable gain RF amplifier that feeds a mixer that is coupled to the regenerative detector by means of a variable coupling that can be selected from the front panel....

I have a stepped attenuator similar to ones we all see in ARRL handbooks and other project websites. It consists of 8 DPDT switches and pads in the 1, 1, 2, 2, 5, 10, 20, 20dB ranges. You can use it to provide a total of 61 dB or any value in between.

I like the double-tuned method of bringing signal into the detector. I also like the idea of making a regenerative detector at, say, 1.8 MHz or so and then down-converting the incoming signal with a local oscillator. Maybe 1.8 MHz would be a bad IF but I'd have to think about it.

Dear amigo Ed AD7TE and other list members

After many experiments with the really amazing REGENERODYNE receivers.... here are some of my findings...

You want to enclose the regenerative detector stage inside the best possible shielding... That meaning a totally closed box with the voltages coming in via feedtrough capacitors, shielded wiring... decoupled plate and screen supplies ... You want that regenerative detector to be absolutely deaf... that is unresponsive to any signals trying to reach into that box that are not the signal coming from the output of the mixer at the front end. You test the quality of the shielded enclosure at night, with everything connected and NO SIGNALS within the detector's tuning range may be picked up. The ZL2JJ regenerative receiver mechanical construction gives a very good idea of what I am talking about here.

After many experiments, my choice for the detector tuning range is from 2.0 to 3.0 megaHertz for a one megaHertz tuning range, and a bandspread tuning from 2.0 to 2.5 megaHertz for slowly scanning by hand 500 kiloHertz...

Now let me explain... For an excellent 40 meters band receiver... you will need a 5.0 megaHertz quartz crystal, and the detector tuning range from 2.0 to 2.5 megaHertz, or even narrower from 2.0 to 2.2 megaHertz to tune the first 200 kiloHertz of 40 meters that are now supposedly exclusive for amateur radio around the world ... unfortunately this not true, as there are still some broadcasters using frequencies from 7.1 to 7.2 megaHertz.

If you carefully scan the HF segment between 1.8 and 3.5 megaHertz, you will exclude the 1.8 to 2.0 megaHertz if there is 160 meters band activity at night in your part of the world... in case you are not able to make a work of mechanical engineering art with fingerstock beryllium contacts for the top cover of the enclosure... 2.0 to 3.5 will give you a 1.5 megaHertz tuning range, that is quite good and an area of the HF spectrum that shows very little use nowadays , now if you have access to many good quality quartz crystals..you can increase the coverage of the receiver--- i.e. 10 mHz crystal will cover 12 to 15.5 megaHertz tuning range ... that includes the very popular 20 meters amateur band... A 8.0 megaHertz crystal will cover from 10 to 13.5 megaHertz , good for picking up the popular 25 meters international broadcast band that spans from around 11.6 to 12.2 megaHertz nowadays...

Opinions on this topic are invited !!! Pass along your personal experiences with the regenerative and regenerodyne receivers !!!

In my experiments, I also found out that the 5 megaHertz oscillator feeding the balanced mixer must be very clean from a spectral purity point of view, because you do not wave harmonics from the oscillator to reach the mixer...

By the way, my favorite regenerative detector circuit is the HARTLEY, using a pentode tube, with screen grid voltage control of the regeneration... Polishing the circuit I found out that the grid connection to the tank coil placed about 15 to 20 percent down the coil instead than at the top, was a good idea too...

My 2.0 to 3.0 megaHert tuning range original prototype detector is very sensitive and has a very smooth transition to reach the point of near oscillation, at the very edge of oscillating , something that provides very good selectivity... In a similar regenerative with a tuning range from 500 to 1500 kiloHertz built experimentally, it was possible to tune the upper and lower sidebands of AM broadcast stations...

Finally the power supply that you want for the REGENERODYNE or for a straight regenerative vacuum tubes receiver does require very good engineering... You want well regulated , well filtered DC on the filaments.. And a very smooth high voltage supply that if possible may be electronically regulated ....

> I also like the idea of making a regenerative detector at, say, 1.8 MHz or so and then down-converting the incoming signal with a local oscillator. Maybe 1.8 MHz would be a bad IF but I'd have to think about it.

Classical _band-imaging_ receivers -- http://dpnwritings.nfshost.com/ej/goodman_receiver/
http://dpnwritings.nfshost.com/ej/goodman_receiver/
-- used a detector operating at a spot frequency below or in the 160-meter band. The cool thing about this is that you can get two-band coverage with just one local-oscillator tuning range. A classical approach used a 5.2- to 5.7-MHz LO to convert 80 and 40 meters to 1.7 MHz with a regenerative detector, sometimes used non-oscillating and accompanied by a separate BFO, operating at that frequency. Nowadays 1.7 MHz is the uppermost carrier frequency in the :AM "expanded band," so I recommend _not_ using 1.7 MHz--even 1.843 MHz, for which cheap "clock rock" crystals are available for BFO and/or crystal filter experimentation.

My BG-4 superhet uses a homemade diode-ring mixer (with two-2N3904 post-mixer amp) and rebuilt Kenwood 4.9- 5.5-MHz VFO to bring 80 and 40 meters down to 1750 kHz. Harmonics from its oscillating detector make nice band-edge markers at 80 and 40, and anyway I never operate right down to the band edge anyway.

1843 kHz is a worthy IF for an 80/40 band-imaging CW receiver because the second harmonic of that frequency is above the 80-meter CW band (even if, as FCC may do "soon," the 80-meter subband upper limit is moved to 3650 kHz as a result of a rulemaking in progress).

And BTW a minimum-loss/"Cohn" CW filter with two 1843-kHz clock rocks and three 100-pF capacitors--910 ohm terminations--will be 200 Hz, or less, wide at its nose. Just sayin'... :-)

Best regards,

Dave

Ed wrote:

> So the signal levels from a good outside antenna need to be reduced to avoid overloading the regenerative detector. In all of the AM regens I've built, I've never had to do this and I never noticed any problems. What is different here?

Correspondent Weeber has summed it up well, but one more aspect is worth mentioning: "AM" reception as we traditionally think about it (demodulation AM with a _non_-oscillating detector) is significantly different from CW or SSB reception in that traditional "AM detection" involves use of the signal's own "carrier"--the central unchanging signal between the an AM signal's two mirror-image information-carrying sidebands--to heterodyne the sideband energy back to audio from RF. For the signal's own carrier to do the heterodyning work well, the signal must be strong enough to overcome any threshold effects in the AM detection device(s), be it/they a grid-leak detector (as in a classical vacuum-tube regenerative detector) or a traditional diode detector (as in a crystal radio, or the "AM detector" at the back end of the IF amplifier strip in a classical general-coverage receiver).

When, however, we supply the heterodyning carrier _locally_ for CW or SSB reception--or for AM detection with the signal carrier tuned at _zero beat_ so our locally supplied carrier supplant's the signal's own carrier--threshold effects are usually absent and we can hear all the way down to the band-noise floor.

So it is that a non-oscillating regenerative detector is generally considerably less sensitive than an oscillating regenerative detector. Or, to put it another way, a non-oscillating detector needs a much stronger signal for good AM reception than a detector that's oscillating for CW or SSB (or for AM reception with the incoming-signal carrier tuned to zero beat with--to the same frequency as--the detector's self-generated carrier.).

From this is follows that a non-oscillating detector is harder to overload in an audible way, whereas an oscillating detector can be overloaded in multiple ways, one of which--as b_weeber detailed--involves the frequency of the oscillating detector tending to be _pulled_ toward the frequency of the incoming signal as a result of oscillator physics.

I find, by the way, that for minimal pulling--or maximum pulling resistance, take your pick--dimensioning the detector-tank L and C such that their reactance is 100 ohms or less at the operating frequency is called for. Operating the detector at a lower frequency rather than a higher one also increases pulling resistance.

BTW, from the heyday of the regenerative detector I reproduce in my radio web pages the article "But Not for Voice," a writing that discusses the differences between "AM" (non-oscillating) and "CW" (oscillating) reception with regenerative detectors (http://dpnwritings.nfshost.com/ej/regenerative_receiver/kruse_but_not_for_voice.htm http://dpnwritings.nfshost.com/ej/regenerative_receiver/kruse_but_not_for_voice.htm).

Full disclosure: I happen to be entirely uninterested in using regenerative detectors for "AM" demodulation, concentrating for two-way work on CW (Morse code) operation as I do, and so my regens have been optimized for detector-oscillating reception only.

Best regards,

Dave

On the topic of front-end attenuation, an experimenter at cqham.ru recently suggested the use of a bridge circuit to achieve attenuation. I thought this was an interesting idea that I hadn't seen before in most simple regen designs; most simple regen designs I've seen just use a variable resistor as a voltage divider to attenuate the antenna signal.

On the cqham.ru thread, it was claimed that with the bridge circuit, 60 dB or more attenuation was possible, if everything is built perfectly (good bridge balance, good shielding, good-quality variable resistor with minimal parasitic capacitance and/or compensation for the resistor's parasitic capacitance).

The discussion is here: http://www.cqham.ru/forum/showthread.php?14624-%CF%F0%EE%F1%F2%FB%E5-%F2%F0%E0%ED%E7%E8%F1%F2%EE%F0%ED%FB%E5-%F0%E5%E3%E5%ED%E5%F0%E0%F2%E8%E2%ED%FB%E5-%EF%F0%E8%B8%EC%ED%E8%EA%E8&p=1311410&viewfull=1#post1311410 http://www.cqham.ru/forum/showthread.php?14624-%CF%F0%EE%F1%F2%FB%E5-%F2%F0%E0%ED%E7%E8%F1%F2%EE%F0%ED%FB%E5-%F0%E5%E3%E5%ED%E5%F0%E0%F2%E8%E2%ED%FB%E5-%EF%F0%E8%B8%EC%ED%E8%EA%E8&p=1311410&viewfull=1#post1311410 , and the proposed bridge circuit is here:

** I never noticed any problems. What is different here?

A detector reaches it's best sensitivity for AM, if either the regeneration is just at the point or a tiny little bit into oscillation. Then it beaves a little bit like a synchron detector. When oscillating, the detector tends to lock into a strong signal. This behaviour is an advantage, when receiving AM signals, otherwise often you would hear a heterodyne tone.

When receiving SSB, the detector has to oscillate at one particular frequency ~1.5kHz away from the center of that receiving signal, to act as a BFO. Low frequencies of a voice are only 200-300Hz away from the detector frequency and sometimes they are strong, so the detector is tending, to lock into them. Now the detector is overloded.

To avoid/improve overloading:
- reduce the coupling between preamp and tank circuit
- build a tank circuit with a low impedanc (low L, high C values)
- turn the regeneration into a stronger oscillation
- when receiving CW, turn the detector frequency to a higher tone >= 1kHz
- use an rf attenuator and turn the signal down to just above the noise level.
- shielding the tank circuit, to avoid direct reception
Being able, to change the amplification of the preamp from +6dB to -40dB, would be perfect.

Best regards,
Bernd

27253. how to replace an electret microphone with a direct line in

I have a small digital recorder that uses an ELECTRET microphone as input.
I would like to feed that digital recorder with a output from an MP3
PLAYER.

Can anyone advise me how to cut off that microphone and feed those two
wires with a line level audio signal?
I don't have any way to trace or produce a schematic for the digital
recorder so I just want to interface
where I can get to those two wires for the electret microphone.
I was considering replacing the electret microphone with a 600 ohm one
to one audio transformer to isolate the two circuits.

Biggest concern is that you need to remove the bias current source on the microphone circuit. Usually, but not always a resistor if about 1-2KOhms. The microphone input is AC/capacitor couple so the bias current is not present on the pre-amp input.

Give it a try with directly connecting to the microphone input and be careful of your signal level going into the pre-amp. Too much will overload it and the recorded audio will be distorted. If hum is detected, then you may wish to add a coupling transformer to break the ground loop condition.

I built the 7.16 Resonator Radio, VK3YE mods by KB3BYT. It works, volume is acceptable for me without the darlington preamp in the circuit.

Here is the radio I built: http://www.learnmorsecode.com/716/716.html
http://www.learnmorsecode.com/716/716.html

Not wire wrap but Manhattan style, audio straight into an LM386 amplifier. Listening to 40M CW, tunes about 7-7.06.

Regeneration control is well behaved and the tuning is smooth with a 100 pF Air Variable I had.

Pictures later.

Michael,

The circuit was Rob's circuit here: http://www.learnmorsecode.com/716/VK3YEmodKB3BYTv2.jpg
http://www.learnmorsecode.com/716/VK3YEmodKB3BYTv2.jpg
I used the same component values as shown in this schematic. The Audio output goes to the AF amp from the "simple" regen. I removed everything else from the board and built Rob's circuit Manhattan style.

A very unusual regenerative receiver in which there is very much RF amplification between the regenerative stage and the detector stage. But beware the high frequency roll off at higher shortwave frequencies due to the Miller feedback capacitances between the collectors and the bases of the 2N3904s.

Well, for quite some time now the shack clock has 'synced' exactly 12 hours fast. That is, 8:00AM shows as 8:00PM. No big deal (I have it set for 12:00 hr display, it wouldn't do "GMT") except that half a day each day the date and day display also is bonkers. Also, the daylight savings time feature doesn't display (I can manually set it, but when it syncs it goes away). . .

At first I thought that the 60kHz receiver may have died and it's not syncing each night, but that's NOT the case. It seems that NIST changed their format just enough (adding phase modulation as well as Amplitude modulation) to make many, if not all older 'atomic' clocks obsolete. They even say so on their web site.

It's a very nice large clock, displaying room temperature, day, date and time. Oh well, I only paid a little over $20 for it many years ago (maybe 15 years?). Guess I got my service out of it. After all, it's only money (which I don't have a lot of, LOL).

I have two ‘atomic clocks’, one maybe 17 years old and the other maybe 12, and no apparent problems with either to date.
The older one sounds similar to yours. Spent $20 on it at the big box store and i reckon it’s one of the best $20 purchases i ever made.

BTW, not connected with above except for the 60 kHz ref: at a hamfest recently i bought a Palomar receiving loop antenna base and two loops.
One was stamped ‘WWVB’ and per description tunes something like 40 – 150 kHz. This loop had written on it in marker ink, “2-30 Meters”.
I wonder if the buyer made a big mistake? I wonder if he was surprised there was so little to hear on this band.

Well, for quite some time now the shack clock has 'synced' exactly 12
hours fast. That is, 8:00AM shows as 8:00PM. No big deal (I have it
set for 12:00 hr display, it wouldn't do "GMT") except that half a day
each day the date and day display also is bonkers. Also, the daylight
savings time feature doesn't display (I can manually set it, but when it
syncs it goes away). . .

At first I thought that the 60kHz receiver may have died and it's not
syncing each night, but that's NOT the case. It seems that NIST changed
their format just enough (adding phase modulation as well as Amplitude
modulation) to make many, if not all older 'atomic' clocks obsolete.
They even say so on their web site.

It's a very nice large clock, displaying room temperature, day, date
and time. Oh well, I only paid a little over $20 for it many years ago
(maybe 15 years?). Guess I got my service out of it. After all, it's
only money (which I don't have a lot of, LOL).

From: les.au49@...
Topic: 27267 Message: 27267

Vladimir Novichkov published an article "Frequency compensated LC networks for oscillators with the wide tuning range." At the end of the article he presents a circuit for a two tube receiver covering the frequency range 3.3 to 9.0 MHz.

He also provides a link to two u-tube videos where he demonstrates the operation of his receivers. The performance he gets from this set is astonishing in this respect: Tuning from 3.3 MHz to 9MHz he barely touches the regen control. He calls this feature "zero-tilt".

There are some difficulties with this receiver - specifically he has spent many hours 'tweaking' the circuit to get a flat response. Another is the tube he uses - 6AS6 "dual control" Clearly this receiver is well suited as the tunable IF in a regenerodyne receiver. So - I say forget the difficulty and build your own version of this design. It's superb! Suddenly I have become converted from the (Jones) super-gainer to regenerodyne.

Later (I can't give a reference) Vladimir presents other work on u-tube, showing other aspects of his study. In particular he presents a very convincing demonstration of variable selectivity with (I think) a later receiver. I don't understand the full significance of this - but it's interesting.

His work is so good, so astonishing - no one interested in regenerative receivers can ignore it. That's what I think.

His work is discussed in depth on theradioboard.com on these two receivers as well as solid state versions. I intend to build the fet version of the variable bw version this winter as soon as I get my basement shop set up. I'm intrigued by the concept and would like to experiment further with it.

Topic: 27267 Message: 27269

Hello Paul,

First, I had no idea - none at all - that the circuit for a solid state version of this set had been published.

Next, I have a 2 'tube' set on the work-bench beside me that could serve as a starting point for such a receiver. It uses x2 6AK5 'toobs' - and the only difference between the base connection for the 6AK5 and the dual-control pentode is this: the 6AK5 connects G3 internally - the 6AS6 brings the 6AS6 to an external pin. My set uses the 6AK5 as (1) mixer and (2) detector - so you can see this will be a very convenient set to modify. (Or perhaps I should NOT modify the set I have. Perhaps I should keep it as a point of comparison?)

I will be more than interested to see/hear the result of your work. In my view (a view without any experience) this work by Vlad stands with the work of Frank Jones (he promoted the regen superhet, the Super-Gainer) and Garys' work with the regenerodyne. I think it makes a regenerodyne a practical set for on-air use for the basic home constructor. (I use the word, "on-air" to mean for 2 way communication, either SSB or CW.)

I have several questions. (1) Is there any chance of using a more common tube as the 'dual control' detector? e.g. 6AU6 or 12AU6 (or even a triode/pentode, such as the 6U8?)

(2) If some-one built a conventional "Jones" superhet, (fixed IF) would the 'no-tilt' circuit be an advantage? (I ask this question because I do not understand - at all - the control system that varies the tank circuit "Q".) Perhaps the AGC voltage generated would be a distinct advantage over a conventional Hartley detector? On the other hand, looking at the feed-back mechanism that provides 'no-tilt' regeneration, the principle of operation is both obvious and clever at the same time.

(3) How many others have build a (very solidly constructed) "VN" type receiver? (I think we need a name for this circuit, and I put forward the name "VN" detector. This is such a good circuit that I expect many more will be built, and it deserves a name.)

In terms of finding more information on "The Radio Board" - I used the clue you gave and searched for "The Radio Board". Then I used the link to "forums" and after that I searched for the name VladN. That got a good response, and I'll read these carefully. Alternately some-one might try this link: http://theradioboard.com/rb/index.php
http://theradioboard.com/rb/index.php

Thanks for sending those pointers (or links) Paul.
Very helpful.

27270. Practical regen for on air use

Yahoo group: regenrx (2016 — 2017)
Date: 2016-10-21 10:12:42 UTC
From: dulmagedon@...
Topic: 27270 Message: 27270

I BTW take real issue with the concept that a regen is somewhat impractcal for on air use. Probably because I often use one of mine for such activity. A hartley based regen can be a real joy to run and lacks many of the bad habits of Armstrong style rigs. It rarely needs a touch on the regen control and can hear stuff your mega$ modern rig never will. Its biggest drawback . Too simple for most. Too few parts so how could it be any good concept. Someone once said they don't get such results. I never said it but I thought in my heart "Because you won't built it this way". Everyone wants to out think the next guy. First built it the way we know works and Then play with it to your hearts content. You will be amazed though or perhaps disappointed the number of times you discover the old simple design works better if you are honest with yourself . Anyway if Vlad design for instance interests you , build it. Exactly as he said at first. Not fair to judge it by postulating or building a variation of it. Regens can be finicky in design so follow his build exactly at first. Should only take a day or so and a few $. And if when you reach the playing around stage and you try something that sets it back be man enough to restore it to original design before going on.

Digikey has them as well:

http://www.digikey.com/product-detail/en/murata-electronics-north-america/CSTLS7M16G53-A0/490-12586-1-ND/5797568 http://www.digikey.com/product-detail/en/murata-electronics-north-america/CSTLS7M16G53-A0/490-12586-1-ND/5797568

I wonder if anyone has used resonators in the Colpitts configuration. The resonator-regen circuits I've seen so far connect one end terminal of the rez to the tuning C, the center terminal of the rez to common, and the other end terminal to/toward the detector active device. This puts the rez and tuning C in series to common, with one of the resonator's internal Cs in parallel with the tuning C and the other from the detector input to common.

Considering this, we can see why in some rez-regen demos, the detector stops, or gets close to stopping, oscillating at the low-C (higher-frequency) end of the tuning C's range: The less C in series with the rez to common, the more the detector is starved for feedback through the rez.

Turning the resonator "sideways" -- one end terminal to common, center terminal to device cathode/source/emitter, other end terminal to common -- would support using the rez in a Colpitts circuit, preferably with external augmentation of the part's relatively small internal capacitances (15 pF each in the part linked above). Getting maximum tuning range in this configuration might require a two-section tuning C.

Well, I didn't ignore and did note Vlad's excellent R&D work, but from the standpoint of building a practical regen that's entirely satisfactory for two-way CW communication, in my opinion it adds quite a thick layer of gilt to an already sufficiently beautiful lily as far as I'm concerned.

The issue of detector "tilt"--feedback variation, and hence the need for regeneration-control adjustment, with frequency is (a) a regen _characteristic_ and not a problem; (b) a non-issue if you use a regen at a fixed IF; and (c) a non-issue in even in tunable ham-CW-band-only regens if you operate as I do with regeneration set considerably above critical. This is the case with the 80- and 40-meter versions of the circuit at http://dpnwritings.nfshost.com/ej/wr/ http://dpnwritings.nfshost.com/ej/wr/ : I just set regeneration at one spot and forget it -- for weeks, even months at a stretch if I don't happen to jostle the control while swapping gear in and out of my on-air lineup. And this is so even when, as is the case with my 40-m regen, I switch in enough C to bring the tuning range down far enough to listen to New York Radio/Gander Radio VOLMET SSB voice transmissions at 6604 kHz.

In the 1920s and 1930s, lockstep usage of regens -- built with tubes that had quite low amplification factor and transconductance compared to those of a decade or two later and beyond -- had hams using separate transmitting and receiving antennas, with the receiving antenna often just a hank of wire "around the picture molding" as the cliche goes. In those days, operating one's regen just above critical regeneration for maximum gain and sensitivity made sense.

Nowadays, with the local RF environment much, much noisier as a result of computers, switching power supplies, light dimmers and lamps that contain internal switching and/or RF-oscillator-driven power supplies, using the transmitting antenna (commonly positioned as far away from such noises as possible, and fed with coaxial cable or balanced line through a transmatch) for reception is good engineering practice. Using a regen for two-way work in such a system then requires (a) low-impedance antenna input and (b) as result of the relatively high signal levels available from such an antenna relative to yesteryear's hank of wire around the picture molding, RF _attenuation_-- which is to say "intentionally introduced signal _loss_" -- between detector and antenna.

This engineering equation immediately throws yesteryear's "operate the detector for maximum sensitivity and gain" tradition out the window. With that window so opened, the issue of detector "tilt"--feedback variation with tuning--is also subject to defenestration because a regen optimized for strong-signal work with a good antenna is intentionally operated significantly above critical regeneration, at which feedback-level setting _variations_ in feedback with tuning are unnoticeable within the CW portion of a ham band.

Best regards,

Dave

27274. OT: Ordered two new shack clocks (changed the subject line)

Yahoo group: regenrx (2016 — 2017)
Date: 2016-10-21 14:28:51 UTC
From: Phil
Topic: 27274 Message: 27274

Thanks all,

I DID decide to go the old 'retro analog' route and ordered two 12" analog clocks, one for GMT and one for local time. NOT radio synced, and NOT the style that the second hand steps off in 1 second steps with a loud "Tick-Tock" (two of my wife's doctors have the tick-tock clocks in their examination rooms and I find myself saying to myself "Tick-Tock, the mouse ran up the clock". With two of them on the wall right over my head it would drive me batty. It seems that any "atomic" clocks are limited to basically USA (and sometimes HI and AK) time zones, and don't do GMT (you can set them manually, but that negates the WWVB sync function).

I must have looked at over 500 clocks and weighed one against the other, reading reviews etc. It seems that none were 100% "5 rated" and one has to read between the lines. I went to all the local big box stores, but couldn't find anything suitable locally (prefer to support local business).

These are the clocks I ordered, in classic black steel (not plastic). I really like the size (12 inches) as opposed to the more common 10" units. Guess it's the ex-military background and old-phart status I fit in At least these won't go obsolete if WWVB changes the time code again.Despite the name, they're Chinese (as is about everything now-a-days.

Yes, I also find the work very interesting and entertaining. I find his work beautiful not necessarily because it is practical, but rather because it applies logic, mathematics, and engineering to wrestle under control one of the regenerative receiver parameters (the tilt) that is normally considered uncontrollable.

I personally and have successfully built several prototype receivers using these methods. As was already noted, there is a lot of discussion (much of it from me, as I was asking Vladimir several questions) on TheRadioBoard.com.

My advice to you is to first build a regenerative receiver based on a Vackar oscillator. This is easy. Then, confirm that the tilt is opposite of the "normal" tilt, i.e. the tendency for oscillation will decrease with increasing frequency.

Then, modify your circuit to remove the Vackar feedback path (make the Vackar feedback capacitor something like 100 nF) and in the other "class 1" feedback path (Hartley, Armstrong, or Colpitts). Then, verify that the tilt is "normal", i.e. tendency for oscillation increases with increasing frequency.

Once you have achieved this, then simply balance the two feedback paths and adjust the total feedback level. The key concept (read it a few times until you "get" it) is stated by Vladimir here:

http://theradioboard.com/rb/viewtopic.php?p=39865#p39865
http://theradioboard.com/rb/viewtopic.php?p=39865#p39865
He says: "Increasing tickler turns and decreasing C28 [Vackar capacitor] increases the total feedback. Changing only one of the two values changes both the tilt and total feedback. Changing tickler turns and C28 [Vackar capacitor] in the same direction changes the tilt."

I find it useful to think of the feedback paths in terms of reactances: decreasing the reactance of the Vackar feedback path reduces the amount of Vackar feedback. Decreasing the reactance of the tickler coil reduces the amount of Armstrong feedback.

> In particular he presents a very convincing demonstration of
> variable selectivity with (I think) a later receiver. I don't
> understand the full significance of this - but it's interesting.

The idea and significance are simple: keep the amplifier always in class A operation, and limit the oscillation amplitude not by driving the device into non-linearity (which is

poorly-characterised and difficult to control), but instead by having a separate active device (another tube or another transistor) that acts to limit the oscillation amplitude. Then, importantly, this separate limiter must act according to a well-characterised and scale-invariant compression law. This means that no matter how large or how small the oscillation amplitude, the amount of gain compression must be the same. If this condition is met, then even as you adjust the oscillation amplitude above threshold, the bandwidth of the oscillating regenerative receiver *will not change*. The above-threshold bandwidth depends on the gain compression law, which then determines the ultimate regenerative gain and selectivity. Then, by altering the gain compression law (by adjusting the appropriate circuit parameters), we can adjust the above-threshold bandwidth in a controlled manner.

The takeaway? You have independent control of oscillation amplitude and bandwidth. You can run the regen hard into oscillation without the widening (whitening) of the bandwidth that occurs in classical single-device regens. Hard oscillation is good of course for SSB/CW reception. Alternatively, you can run the regen very weakly oscillating, for synchronous reception of AM by injection locking. And again, you can control the bandwidth *independently of the oscillation amplitude* (by adjusting the limiter parameters).

And finally, another interesting property of keeping the amplifier always in class A (and using a separate limiter) is that the influence of the regeneration control on the oscillator's frequency can be reduced to practically zero (explanation here: http://theradioboard.com/rb/viewtopic.php?f=1&t=5153 http://theradioboard.com/rb/viewtopic.php?f=1&t=5153). Another regen "quirk" understood, analysed, and controlled!

> His work is so good, so astonishing - no one interested in
> regenerative receivers can ignore it. That's what I think.

I agree. Again, it's not so much a question of whether the scheme brings practical benefits or not. It's the fact that these hitherto uncontrollable parameters have been so precisely analysed and so cleanly brought under control. It's a fascinating beacon of light that illuminates previously unexplored areas of regen design.

Just FYI, the experimenters on the Russian forum cqham.ru are quite fond of Vladimir's ideas. Unfortunately, these ideas don't seem to have caught on in the English-speaking world. Apart from the many experimenters on cqham.ru, I can think of only less than 5 people that I know of who have accepted and experimented with the hybrid feedback/zero-tilt ideas.

Zero-tilt is also useful for making an amplitude-stable oscillator for a VFO. This can be useful when making a varactor-tuned oscillator (VCO) where tank voltages must be kept low to avoid tank voltages detuning the varactor. The usual approach is to use AGC. But hybrid feedback allows a simpler, passive, non-Q-degrading approach to evening out the oscillation level in a wide-range VFO.

My final recommendation for thorough understanding is to read, understand, and reproduce every simulation result in Vladimir's papers (in particular the open-loop oscillator analyses and frequency sweeps of peak amplifier response). I have done this (through a long and error-riddled learning process) and my results are mostly posted on TheRadioBoard.com. I can probably assist if you have any questions about running these sorts of simulations to confirm or design for zero-tilt. My personal interest was applying these ideas to 1.2-volt BJT detectors, which I was successfully able to do and which was a great deal of fun.

Enough for now. :-)

One more comment about hybrid feedback/zero-tilt receivers: make sure you use high-quality, RF-grade capacitors for the Vackar feedback capacitance. If you don't, you will introduce unpredictable losses into the tank which will upset the tilt. I didn't understand this at first and spent several days (weeks?) trying to understand why I could never confirm the "reversed" tilt that must be present in a properly-functioning Vackar-based regen. After I finally used high-Q NP0 ceramics, then I started to get the results i expected.

Hence my previous advice: get the Vackar-based regen working first. That will show you if you have something wrong or not (low-Q capacitors, parasitic feedback paths, low-Q coil, etc.).

Best regards,

27278. FS: Heathkit HW30 Transceivers $30 each

Yahoo group: regenrx (2016 — 2017)
Date: 2016-10-21 15:32:10 UTC
From: Bry Carling
Topic: 27278 Message: 27278

Two Meter AM is alive!

FS: Two Heathkit HW30 Benton Harbor Lunchboxes! Crystal-controlled transmitter, and a tunable superregenerative receivers with RF stage. The transmitters with up to 5-watt input are more than adequate for "local" net operations and the communication range of all models is unlimited under "skip" conditions. Other features include: frequency multipliers on the 6 & 2 meter versions to provide straight-through finals from an oscillator using a fundamental crystal in the 8 mc range; built-in final amplifier metering jack, and "press-to-talk" transmit/receive switch on the front panel with "transmit-hold" position.

These are almost complete and being sold "as-is."

Will include docs and a manual copy.

One has a meter added. One has a power cable. I also have the original MICs for these for additional $$.

First come, first served. Your choice if you are first!

TWOers available for $30.00 each plus shipping.

Original Astatic microphone for Twoer = $30.00 OR - if purchased WITH a TWOer, then $25.00 each.

ALSO - I have two 8025 kHz Crystals for use with the TWOer to go on the popular 144.450 MHz AM callling frequency - $16.00 each or if purchased WITH a TWOer, then $10.00 each.

Shipping additional.

I am pleasantly surprised how reliably the ‘atomic clocks’ sync up here, in a high-noise environment and an apartment with high level of
radio wave attenuation.
I have seen the ads for the ‘atomic watch’ and i really wonder how something that small can have an effective 60 kHz antenna.

Subject: [regenrx] Re: OT: Guess I need a new clock for the shack, the old one's 'obsolete'

I had trouble with them -- worked for a couple of years (I'm in
Delaware), then propagation conditions changed and clocks would no
longer sync.

Date: 2016-10-21 21:01:14 UTC
From: Hubert Miller
Topic: 27283 Message: 27283

I harvested a couple tuning caps from an old Link FM deviation measuring instument.
One, 5 pF and the other 25 pF max. Is the 25 a good size for bandspread tuning?
This would make a good vfo cap as the plates are quite thick, not bendable at all.
What about a use for the 5 pF ? Too small except maybe for antenna coupling?

Also, i measured a set of Brush piezo headphones. They show about 1.5M ohm and
500 pF. This is a working set. I know the lit describes the actual capacitance in the
several nF range. I don't know how to account for this 500 pF measurement except
that the low cost tester i used is confused by the parallel resistance. I don't know if
the 2 sides are wired series or parallel.
The AADE tester i tried rejected the test, apparently due to the parallel resistance.

27286. 400 Hz power transformers for audio

Yahoo group: regenrx (2016 — 2017)
Date: 2016-10-21 21:11:30 UTC
From: Hubert Miller
Topic: 27286 Message: 27286

I recently scrapped a microwave signal generator - the fact that it was 400 Hz powered was the decisive factor in the decision.
I got a really nice portable carry case, a bunch of tubes, and three 400 Hz power transformers. The power transformers may
be the best of this lot: they have multiple HV and low voltage windings. I just measured one winding at 20H and by strapping
another HV or two secondary, i'm pretty confident i can get a choke of 35H or so. Also for crystal set experimenting, the
available multiple ratio windings might be nice for trying impedance matching to headphones.
This was an AN/URM-34 signal generator - apparently factory new - kind of sad that it never saw use - but so it goes.

Hello Don,

This topic (use of regen for "on-air" use) is of great interest to me. Incidently "on-air" refers "use with a transmitter", not SW listening. Every time some-one reports, "I use my regen "on air" I take note. This is especially so when the transmitter is home-brew SSB.

I'm interested to read that you find the Armstrong circuit has "bad habits" compared with the Hartley. Would you care to share your experience? As for "drawbacks" in building a regen receiver - I think the main obstacle is access to (even a basic) metal-working shop (or experience with metal-working). In the 40's and 50's there were many mechanics shops and at school most boys learnt manual arts - code for metal and wood work. Alas - that's not the case today.

As for building Vlad's design - can anyone here comment on the performance of the Russian substitute (6J10P) for the 6AS6? Ditto for the 12AU6? The 12AU6 is a 7 pin RF pentode with G3 available. (This isn't the case with the 6AK5, for example). But the 12AU6 isn't listed as a "dual control" tube - just a regular RF pentode. At any rate, if these don't work (with some adjustment of bias) I can buy and substitute the 6AS6. The price of the 6AS6 is quite reasonable. Postage is expensive.

Les

Hi Les,

I used the Russian 6as6 equivalent as a replacement for the 6be6 mixer tubes in superhets. It can be used here without any changes in the socket. The only disadvantage may be a not so good isolation between input signal and oscillator. But so far I didn't notice any oscillator pulling, and it works perfectly well. I didn't try it in a regen though.

Best regards,

Udo, dk3bi

From: dulmagedon@...
Topic: 27270 Message: 27299

First I am a mech machinist (Automotive) by profession so I am supposed to have some of those skills however I much prefer wooden radios. I have a twinplex 6sl7 (now uses a 12sl7) and I have used it a lot for communication in my ham station. Usually when using my bare essentials one tube transmitter. I have also used it on AM with my DX60B. It copies SSb just fine as well. Bad habits? Touchy to hand capacity and and regen settings although once It is set up it is very serviceable. However during the course of my years playing with such things I have built a few hartley regens.Usually just whipped them up using the bsic circuit as a base. Some in pursuit of a usable transceiver design. I noticed right away they didn't seem prone to the same problems and I got to like them Currently I have two that I am very happy with. One uses a 56 tube and a 58 and is surprisingly stable. It is a very usable radio for Ham work. In fact I operated it in the Linc Cundall event this year with success. The other that still surprises me is the one I built when i was doing my take one tube transceiver in the Weskit style. I didn't like the weskit circuits so just did my own. Both (tx&rx)hartley based. That receiver stuns me with how well it works. I added a 6aq5 for extra audio but it was usable before and the circuit is so basic one would wonder why it works so well. I would not condem the Armstrong. In fact my slugabsorb is sort of Armstrong based but I just really like how the Hartley based circuits work. They also seem to have less of a telltale emission even when listening for CW or SSB. I rarely if ever have to fiddle with the regen pot when tuning a ham band. Both by the way are on 40M. The transceiver one uses a European tube. Tis an odd number with an extra letter in it prefix. Since I have not had to touch it since building it I have already forgotten the number but will check next time I am in the shack. EAC84 perhaps but let me check. That tube I chose because it is a dual triode with one half power and one half voltage style .I use the voltage side for the regen and the power side for the transmitter . The transmitter circuit and rx circuits are virtually identical except for grid leak values and the regen control. The rx runs though on reduced voltage.
Other then that all I can tell you is from the moment I put voltage to it I have been satisfied with it. I would like to get it on 80M as well and was working toward that end yesterday but am most careful not to upset it so any changes are instantly reverseable. I see parasets mentioned above I am also deep into spy radios . My favourite is the German Adapter set which I often have on 40M CW however since there is no regen involved I wont say much here.

Topic: 27270 Message: 27301

Thank you very much amigo Udo from Germany

I wonder if the last two letters after the dash EB are important...
because I see 6ZHE2P, that is 6Ж2П tubes here locally , but without the
EB at the end.

By the way , the 6ZHE1P are identical to the 6AK5 and 5654 tubes. The
fact is that the cyrillic letter Ж is transliterated to zhe in the
latin alphabet.

In a typical well built the performance of Hartley circuit using screen
grid regeneration control with the 6ZHE1P/6AK5 is a good as you may want
a regenerative detector to work, especially between 500 kHz and 5
megaHertz tuning range. In my REGENERODYNES... the Hartley detector
tunes from 2.0 to 3.5 megaHertz, and the bandspread function tunes from
2.0 to 2.3 or 2.0 to 2.5 megaHertz for very smooth easy tuning...

Don – the single tube trans-receiver: how much power into the transmitter section?
Do you notice at all, any receiver drift due to heating of the transmitter triode in the same glass?
I’m just wondering. The Weskit only ran 2 watts max, i think, and probably less than that at
practical battery B+ voltage.
thanks-
Hue

Attachments: 1 described; binary payloads are missing from this source WARC

Not that I have noticed Hue, so I can only say it has not yet been an issue. I am still at the enjoyment stage so haven't got down and dirty checking it. The only similarity to the Weskit is the single dual triode. It is my own circuit. When I put it on the air Paul N1BUG came back almost immediately. That is quite a haul for the little rig.
I think well over 400 mi ATCF. I made the rx section with one less plate in its cap and added a small bandspread cap to even the score and so I can move a bit looking for replies. It is single tuned (dual gang variable cap). To be honest I don't know why it works so well. I am a bit surprised. It is pure joy to run. So much so I am afraid to monkey with it much.

I dont think I have drawn one yet. Just a normal hartley osc. Coil centre tapped to cathode. TX and RX share the same RFC . B plus is switched to decide which side is being used. 6aq5 amp is nothing special. Runs about 1/2 throttle.

27307. mcMurdo-Silver 801 Final report

Yahoo group: regenrx (2016 — 2017)
Date: 2016-10-22 23:56:07 UTC
From: Richard
Topic: 27307 Message: 27307

Firstly, there is serious interaction between Antenna Tuning and Main Tuning, probably because of magnetic coupling between the coils. They are 1.5 inches apart with a small shield and the shielded 6BA6 RF tube between them. There is no remedy there.

I remembered Don Mix in "The Novice Special," QST June 1956, notes that high gain RF pentodes have a small dynamic range, little output, and are difficult to control, so I substituted a 6AK6 for the 6AU6 with beneficial results, greater dynamic range and much more output.

The set was pulling 40 ma at 180 volts which seemed excessive, so I measured the tube currents.

6BA6 RF amp. 23 ma. 6AK6 detector 1 ma. 6C4 1'st AF 1.2 ma. 6AK6 AF output 15 ma.

The 6BA6 RF stage has a design flaw putting 180 volts on the screen, which should be about 100 volts. I added a 27k dropping resistor and screen bypass.

Backlash in tuning: The tuning capacitors are MPC types with extended shafts, and have significant friction. I played with penetrating fluid and oil, with insignificant results, and think they were meant to have friction as they were primarily screwdriver set capacitors. The tuning drive has spring loaded backlash gears, but the capacitor friction causes inevitable lost motion.

It works best with an external (larger) speaker as the built in 2.5 or 3 inch speaker is less efficient. Changing the 6C4 to a dual triode for another AF stage would give better audio.

Conclusion: It works tolerably well from 90 to 180 volts, but is nothing to get excited about. I've learned a lot, but it's time to move on. McMurdo-Silver must have been in chaos when this was put out, a badly designed barely-working receiver.

Richard, AA1P

Thanks, Richard, for the 801 review. It always astonishes me when i learn about some design flaw in a product,
particularly so for apparently pretty obvious items (such as the screen resistor here.)

I have not read a lot about McMurdo Silver's electronics enterprises – i suppose i should, to fill in the blanks.
But he certainly tried a lot of different things and to me, at least, seems never to have really found big success,
whether aiming at the top, middle, or bottom of the market.
I had a couple of their VOMAX vtms at one time – i wish i still had them – i gave up too easily, and didn't
realize the schematic was even published in a QST article during the 'war years'.

I have somewhere (i think) the chassis of their VHF 800-series receiver. Has kind of homemade-looking tuning
capacitor.

The other thing I notice about hartley based regens is they are not over sensitive to antennas like the others. You can use your transmitting antenna with them. You can see in the photo the switch. It switches the B+ from the RFC to TX or Rx but also switches the Antenna from the Tx to RX side (DPDT) my armstrongs don't like or need that much antenna which is fine but when operating a transceiver it is nice to only need one antenna.
This rig seems to suit me well.

Writeups (search by your favorite means) report that McMurdo Silver had suffered significant financial reversals by 1940, and took his own life in 1947. So the postwar years for him were not a time of sunny innovation.

From: Leonard Meek
Topic: 27320 Message: 27320

Stop me if you've heard this before. Tuning a regenodyne receiver can be challanging, especially with only logging scales to go by. I first find the tuning range of each RF coil I'm going to use. A good RF sig gen and/or freq counter are used, with the peak response shown on an "O" scope or VTVM. The min and max freqs are tabulated on an Excel spreadsheet. Then I measure the freq of the regen detector at each major point on the log dial, and tabulate the readings on the spreadsheet. Finally, I set Excel to calculate the IF freq for any freq I want to tune to, with whatever xtal I have in my measly collection, by subtracting the xtal freq from the desired RF freq; =ABS(RF-Xtal) Checking this against the IF tuning list gives me a starting point to set the detector at. The RF coil that covers the freq I want can then be swept. This reduces the searching by luck for me.

Hi Leonard,

For my RAK-7 and SW-3 I asked the spread sheet to make a smooth curve of dial/frequency for those logging scales with a small handful of points. I don't have to fuss with the computer - just look at a sheet of paper. That also works for an LM without the tuning book. It only takes a few seconds to determine the frequency of a 'found' signal or to preset the radio to a wanted frequency (W1AW?). Both radios will reset very closely to a previously logged signal.

There is no essential difference between a dial marked 0 to 100 and one marked 3.5 to 4.0. It's only a matter of what you are used to.

27326. Another unusual post-oscillator detector circuit

Yahoo group: regenrx (2016 — 2017)
Date: 2016-10-25 22:53:31 UTC
From: Hubert Miller
Topic: 27326 Message: 27326

I was looking online for a review of the Heathkit Tunnel [diode] Dipper HM-10 to kind of learn what to expect if i decide to repair the one i have.
I read this write-up on the Heathkit dip meters at
http://www.w6ze.org/Heathkit/Heathkit_007_HD1250.pdf
on page 3 of 3 there's the schematic for the Heathkit HD-1250 schematic. A bipolar transistor is used as the adjustable dip oscillator
and the detector consists of a DG MOSFET followed by 2 diodes in a fullwave rectifier. One diode takes RF from the source and one from
the drain; one gate is driven and the other, as usual, is + biased. I actually see no advantage in this circuit, except that potentially the use
of a MOSFET minimizes loading on the tuned circuit, but in this example, the gate-ground resistor is not optimized for minimum load at
HF frequencies. (Probably couldn't practically raise it in this instrument because of parallel gate-ground capacitance's effect at VHF.)
Anyway i thought this circuit quite unusual. Maybe i'll even look up the manual and see if it talks about it in more detail.
-H

By connecting an aerial to the dipmeter coil and by adjusting the Sens. potmeter R1 you can use your dipmeter as a regenerative receiver.

Another aspect of that circuit deserves comment: The detector-driving MOSFET is equipped with equal-value drain and source resistors with the aim of developing equal, antiphase drive for the detector diodes, but this approach cannot work as intended because it ignores device physics and the fundamental differences between common-cathode/source/emitter and common plate/drain/collector amplifiers.

To put the "device physics" aspect simplistically, the drain resistor is shunted by the device's drain-to-source impedance (for a small-signal MOSFET, a value on the order of kilohms) more or less in series to common with the source resistor) and the source resistor is shunted by the device's source impedance (a value in the tens to hundreds of ohms). So the circuit's two diodes, one driven from the MOSFET drain and the other from its source, aren't driven from anything like the same impedance.

Even worse for hopes of achieving equal drive levels for both diodes, the MOSFET acts as a common-source amplifier in driving the drain diode and a common-drain amplifier--a cathode/source/emitter follower--for driving the source diode. Assuming nonzero impedances to common in both legs of the circuit, the gate-to-drain path affords some voltage gain, and the gate-to-source path affords some voltage _loss_. Driving both diodes from the same amplifier port -- preferably the drain, which path provides voltage gain -- via a trifilar transformer connected to drive the diodes in push-pull would have been a better solution.

A multiple-crystal filter I long wanted to try (and ultimately _did_ try) at 1843 kHz (Hugh L. Gottfried, W6YBR, "An Inexpensive Crystal-Filter I.F. Amplifier," February 1958 QST, page 18, ported from 1690 kHz to 455 kHz in Chet B. Opal, K3CUW, "Simple Crystal Filter," March 1964 QST, page 64) also embodies this "equal cathode and plate resistors equals equal but opposite output" misunderstanding. Author Gottfried's finding -- that the value of his filter's "phasing" capacitances was "not critical" -- is directly contrary to the behavior of the phasing capacitance in a classical, well-balanced single-crystal-gate filter, and serves as direct evidence that he did indeed not achieve the equal but opposite drive he sought. But not to worry: What he *did* successfully build at 1690 kHz is a buffered version of what we today commonly employ -- with careful attention paid to intercrystal, coupling-controlling capacitances to common, because buffer amplifiers are usually not employed between its multiple crystals -- as a ladder filter!

Best regards,

Dave

I would return the gate resistor R23, 100k, directly to the source. That would end the situation with the source-follower output, and not greatly
upset the bias since the source is at +1 volts. Gate2 can be adjusted for to compensate if necessary. The source and drain resistors are low value, 350
ohms, which is very low compared to the drain impedance of 100-200k. That will tend to give equal outputs over a large part of the very large frequency
range the buffer will work at. Buffer output will start to fall off at around 100 MHz anyway, where the device and stray capacitance start approaching the
impedance of the 350 ohm resistors. Due to the wide frequency range 1.6 – 250 MHz (7 octaves?), transformer coupling i think is a very challenging
proposition. This circuit is not automatically to be filed as ‘cannot work’ as it’s well established in a variety of circuits from AF to RF and in commercial
equipment too, not just the HD-1250. Even as-is, if the output at the drain becomes very low, the source-follower output is less affected by device
capacitance and its output gain will tend to stay constant at some level <1 so the buffer achieves its purpose. Being driven by the oscillator its input RF
voltage is in the volts, not at receiver level, so even falling back to the <1 gain at VHF, there is still output to drive the indicating meter.
I bought the manual for the HD-1250 so i’ll soon see if Heathkit provided any pertinent comments in their circuit description. I don’t see any
immediate advantage to using a fullwave rectifier here so i am wondering if there’s more to this than meets the eye.

I am fishing for ideas for a variable inductance coil, where the inductance varies by stretching or squeezing
together the coil, AND is not mechanically very complicated. I'm presently stumped and have no starting
point ideas.
The coil is for a simple VHF receiver where i want the tuned circuit impedance as high as possible. I'd like
to use only self capacitance of the coil, no separate variable capacitor.
I think this would require something like an externally threaded plastic tube maybe 1.5 - 2.5 inches long
and some kind of large nut or coupling to ride the threads and work the compression or stretching.
I'm thinking about 12 gauge wire for the coil.
If you wonder, this is for an FM-band crystal radio.
No - i don't want to machine a tuned cavity, thanks! And resonant lines, too long.
thanks for any input-
Hue

Hue,

How about a string and pulley drive? I'm imagining something similar to a helical filter with the coil anchored to the chassis at one end and connected to the string and the free end. The string would probably have to be a closed loop so that it can pull in both directions. With nothing but a low-loss string, perhaps monofilament, connected to it, impedance at the top could be very high and so could the Q.

I thought about this some more. I need some kind of sliding contact device. The stretchy coil idea isn't best for Q.
When i want less inductance, i should use less wire, since the ohmic resistance otherwise stays the same and the
Q decreases. A few paragraphs in QST i quoted previously demonstrated that shorted turns had little actual
effect on Q.
I recall taking apart some old UHF TV converter that had a circular tuned line with a shorting slider. Maybe if i
can recall some more details of that thing, it will inspire me. ___
I DO have a Q meter that covers the 100 MHz territory but it needs some work....anyway this will be an opportunity to
also use my dipmeters, which i haven't done for a while.
thanks for the suggestions, tho !

Yes, you're right - the stretchy coil idea is a hard way to do what you did for a variable inductor.
And since the frequency range of the band i'm interested in is only 1.25 : 1 the Q will not change
that substantially between the frequencies for the same length of wire used. I forgot that. The
shorted turn might do it also and even the variometer idea might be pretty easy for this low an
inductance, 0.03 uH.
thanks for reminding me!

I think what you saw may have been a Mallory "Induc-tuner" (I think I have the name right), popular in the late 40's and early 50's. Probably hard to find info on the gadget now, but it was used in fairly wide range VHF tuning units, as an alternative to rotating "turret type" tuners. Some vintage VHF communications receivers (Nems-Clarke) used this system. They were used in USAF tracking stations, such as the one at Vandenberg AFB (the Pacific Missile Range) in California, and tuned roughly 50 to 275 MHz. I worked there in the 60's and 70's. If you find someone with a fairly comprehensive junk box they may have one.

You may be able to find pictures on Wikipedia or some similar place.

I do have to ask why you are attempting to build a VHF FM crystal set. You do realize that FM does not detect properly with a standard diode detector. Yes, a method called "slope detection" can be used, but to do so requires significantly more selectivity that the "Q" of a straight diode detector offers. A simple super-regen will work reasonably well. Such a design appeared in Popular Electronics magazine in 1964 (don't remember which month, could have been April. Wow - that was going on 60 years ago!) Regeneration serves to significantly boost the "Q" of a tuned circuit, of course.

Used a single 6C4, which I built and was surprised how well it did. This was in the days when the FM BC band was significantly less populated than it is today. Not too sure how it would do today, but I do encourage you to try it. A transistor version would be fun too.

Somewhere i have a little radio i think maybe was a kit or semi-kit of some kind. It does cover the FM BC band and uses one acorn tube and a transistor
amp with one CK722.
The reason i am interested in the "FM crystal radio" is that a few other people have reported success with it. I mean "relative success". For many years
it was considered not do-able. I was reading on the "Radioboard" website recently about a Chinese tourist's crystal radio testing in some eastern
metropolis. His handheld FM crystal radio only got one station, but it DID work. Yes, it does call for maximum Q if you want to get any volume. That's
the big challenge. The little superregens i think work okay for FM because of the fantastic sensitivity of the superregen circuit despite also having to use
slope detection. (I think i recall actually seeing a circuit in an old Radio News mag showing an actual discriminator transformer fed 2-active device (triodes)
superregen detector. I think that would require too much finessing and i don't think with conventional coil Qs this special transfomer would work very well
at VHF.)
Many years ago, living in Seattle i was playing with crystal radio circuit using a single Ge transistor in kind of an enhanced detector circuit - no external
bias tho. For some reason it picked up a local FM station all across the range. I needed to put a small RFC in the antenna lead to block the VHF. I still don't
understand the mechanism of how the FM detection worked.
There were some posts here a couple years back about a circuit called, i think, the Hellendyne, which was a straight regenerative receiver - not superregen -
for the FM band, and the builder reported something like dozens of stations he was able to pick up with it - whereas the wide selectivity of a superregen
would mean you could maybe distinguish only a few stations across the FM band. I had, like most people, believed a straight regen was impossible on VHF,
but i was disabused of this belief years back when i read in "Amateur Radio Techniques" by Pat Hawker, there was a circuit for a 2-meter hamband regen
receiver.

27347. triac circuit excessive heating 1K resistor

Yahoo group: regenrx (2016 — 2017)
Date: 2016-10-28 05:16:38 UTC
From: Rob
Topic: 27347 Message: 27347

I built this night light triac circuit.
During darkness..... the 1K resistor runs cool...
when the triac is ON
http://www.learnmorsecode.com/help/triac/nightlight3.jpg

BUT
during sunshine... or a bright flashlight... the triac turns off like it
is supposed to do
and the 1K resistor cooks..... smokes..and ...burns out.

I replaced the carbon 1/2 watt resistor with a 1 watt metal film
resistor and it did NOT
burn out but it does cook up to finger burning temperatures.

IS THIS NORMAL for this circuit by design?

Should the 1K resistor be replaced with a 5 watt CEMENT power resistor
better suited to give up
the heat?

or is this heating really just a bad idea...bad design... fire hazard?

Thankyou.

I thought is was a capacitor by the schematic but
I never saw one of those before so I was trying to wrap my brain around
how it is made from scratch but the image is not clear enough to
replicate it's
construction.... so I drew the blue air space image... just to ask..if
that is correct..that it is
nothing more than adjustable plates with an air gap??????

Yep, just as couple plates and an air gap (think about it, even the usual classic variable capacitor is nothing more than a group of plates with an air gap.

Now, in some very high power transmitters where the Voltages are extremely high, you'll see something similar, only instead of two plates, it'll have a pair of metal balls (double entendre NOT intended). That is an "air gap" to allow discharge if the peak voltage goes too high. I've seen them on the secondaries of the modulation Xformer in high power AM service, as well as across the HV Filter choke in a power supply. It's there to protect the transformer from insulation breakdown. . .

Rob, to make circuit more energy efficient, the load should receive less power than maximal. To design this, connect in series with R1 a 2W rheostat and adjust tolerable minimal power.

I don't own any 2 watt rheostats.... and
I did experiment with a 20K potentiometer which did spark, smoke and burn.

So what IS the test here..to "adjust tolerable minimal power"...
what test points?
voltage?
amperage?
I am an amateur electronics hobbyist.... not an electrical engineer....
...so please be specific.

You said THE LOAD SHOULD RECEIVE LESS POWER THAN MAXIMAL

which load are you referring to?

the triac controls the LAMP LOAD... which is a 100 watt light bulb.

http://www.learnmorsecode.com/help/triac/nightlight3.jpg

I do not understand how that lamp would... or should RECEIVE LESS POWER

Rheostat means potentiometer connected with two wires as a resistor. A potentiometer with normal size withstand dissipating power 2W. Wattage is printed on it.
You can use potentiometer 5kohm or 10kohm. In such a circuit, the lamp will glow less and you have to judge at what position of rheostat (potentiometer) the light will satisfy your needs.

This is called a neutralizing capacitor. It is a low capacity - high voltage variable capacitor. It's used to cancel/offset the interelectrode capacitance of vacuum tubes.

The neutralizing capacitor provides negative feedback to cancel the feedback effect of the internal capacitance of the amplifier. Without it, the positive feedback from the amplifier's internal capacitance may cause the amplifier to go into self-oscillation.

From: Phil
Topic: 27356 Message: 27356

The following is a copy of the message and last night's log that I sent to the NDB (Non-directional beacon) list. I thought it might be of interest to some here as my homebrewed 1V3 (all tube) regen receiver and Low-Noise Vertical antenna was the only equipment used, NO external audio filters etc. I don't doubt that if I'd stayed up a couple more hours that there'd be at least another 20 or so beacons in the log.

****

Last night I decided to use the homebrewed Regenerative Receiver and do what I call a "Retro" listening session. The set is quite a good performer (for 1930's technology) but like a high performance sports car, it's a set that you 'drive', not just kick back and casually cruise the band. With one hand on the tuning, another one on the regeneration control, a third one on the built in audio filter switch and a 4th on the RF gain control (it helps to be an octopus ;-) it's possible to dig out some difficult beacons. Of course it's still NOT up to the performance of my Icom IC-7200 or R-75 combined with the external Timewave DSP-599 and homebrewed 8Hz audio filter combo.

NOTE: DDP-391 in Puerto Rico was quite strong here all evening, starting quite early. I had intended to stay up past midnight to catch some more, but fell asleep about 2230 local time.

The logs, all from live listening, no remote receivers or 'waterfalls', NO rare DX.

I did precisely what you said with what I had here.... but turns out
they are 1/2 watt
so
popped ...sparked and burned..... just like the 1/2 watt carbon resistor
did.

Thats when I started asking questions here...about actual design logic.

Manufacturer Part No: B10K OHM
Specifications
Adjustment Type: Top Adjustment
Power: 1/2W
Resistance: 10K OHM

27366. Re: The "zero-tilt" receiver by Vladimir Novichkov.

Yahoo group: regenrx (2016 — 2017)
Date: 2016-10-29 11:15:57 UTC
From: les.au49@...
Topic: 27267 Message: 27366

After reading about Vlad's work on a regenerative receiver using the Vackar configuration I decided to build a bipolar version. Not necessarily zero-tilt, but certainly Vackar config. I found a circuit and re-drew it as you see find here:

The directory: https://groups.yahoo.com/neo/groups/regenrx/files/zTemp/
https://groups.yahoo.com/neo/groups/regenrx/files/zTemp/
The file: Rx-1608 ....png

This *may* work; we'll see. The file: https://xa.yimg.com/df/regenrx/Rx-1610%2C+bipolar%2C+minimalist.png?token=K8oxvNfiDb0XFKMeSP-D7vakQrPOXtI1FfXi4eZjjsFWCjQxqU_kAvzfh9JVt-39ehN6dwWjf0vZ7VrsNWMTUoferHpPnsKdpZX_5xnqM8kVXJdnBK4zrEWCkkd22uwJFDbmKLsUpfEjJ2h5mA&type=download

I built the circuit on strip-board, according to the circuit.
The circuit isn't a "no-tilt" design, but I can say that the regeneration setting is fairly level across (a narrow) band, and that the "best-regeneration" setting peaks in mid-band. I need to increase the regeneration control at both the lower and higher band edge.

Results: As built, performance was very poor. For example, I built another receiver using the infinite impedance detector and "Q" multiplier recently. Using this set I could receiver the three local stations on the AM broadcast band using an indoor aerial a few meters long.

Before that I build a 2 "toob" Jones superhet - x2 6AK5 tubes. The detector follows Arnie Coro's preferred Hartley configuration fairly well. I feed the 6AK5 mixer with a solid state local oscillator. Using this circuit I can hear broadcast stations at the low end of the B-C band about 80 or 100km distant during the day with very loose coupling to the aerial. (Maybe a few pf). The adjustment of regeneration on this receiver is silky smooth (as Arnie Coro said).

The new biploar experimental circuit performs poorly, (as it stands at the moment) as I mentioned a few moments earlier. I hear squegging around the point of regeneration. (I suspect decoupling the AF stages may fix that.) Connected to a 30m aerial I cannot resolve ANY of the LOCAL stations at the top end of the BC band. I'm confident the set is correctly tuned; When I advance the regeneration control I can hear the signal from the set heterodyne with the local stations on a commercial receiver. The set is working below and above the point of regeneration.

Despite the poor performance I'm not discouraged. (Stupidity knows now limit!!) I spent some time adjusting the other receivers before getting good results. This set my be the same. I want to compare the performance of different sets based on different technology - tube, FET and bipolar.

For the moment I'm going to make a cup of tea and think a little.

I may have rob. I will look. However It is just a thick stiff copper wire 12 or 14 standing up along side the tube vertical. Bending it till you get it neutralized is all that is required. For the 5 minutes it takes it is well worth the try. Heathkit used t for years and I use it a lot. My linear even has a pair.

I have changed the Darlington pair detector unit of my differential pair Q-Multiplier regenerative receiver. T3 of the Darlington pair has been configured as an infinite impedance detector by the RF bypass cap C13 of 10 nF. T4 functions in this case as an AF preamp which is DC coupled by an LPF with R10 and C14 to the output of the infinite impedance detector.

Don, I use a regen for regular cw communications. Last NRR event (Feb.) I scored eighth highest, with a 25 watt MOPA and a Regenerodyne. Also, I was one of the few that made a lot of those points working France, Italy and Sweden, all on three xtals, 7037, 7045 and 7120. The 5-8kc wide passband at a couple bumps above Threshold was no barrier preventing me from participating in a pile-up. Although a bit of AGC would be nice . . .

It is about to turn 27 years old, I built in in 1990. Flawless, trouble free, it's the most dependable rx I own.

And . . . it's a regen. :)

I am glad to know someone else does full vintage ops. Congratulations . I have several that work real well and a couple of turkeys. I am trying recently to understand what is the difference that makes a good one or a bummer. My worst is the longwave one and next would be the armstrong I built with a pair of 26 tubes . My all time best is the one in the transceiver. I pinch myself everytime I use it. My twinlex I use always with my bare essntials rig. You put up some pretty impressive contact in the NRR . FB.

My favourite for on-air use is this ceramic resonator regen for 7 MHz.

I've worked Canada from Australia in conjunction with a 30w transmitter.

Anatomy of a 30 watt 7 MHz CW regenerative transceiver (and a DX demonstration)

Very impressive. I like how your cer /res tunes. Also your spotting switch. And BTW you test set up wiring doesn't bother me a bit. It even looks vaguely familiar. I have two solidstate stations. one is very low power , about 1 watt and one is about 8 watts and has a vxo in the TX. I wonder if I popped a cerres there if I could get more wiggle. itis on 80M at colurburst freq and I think I even have one of those in my junk box.somewhere. The RX is the slug absorb regen which works very well. I am tempted to dig it out. The TX acted up last time I had it going so I set it aside till I got abitious. Maye its time I took a few minutes and fixed it. Nice going!
I really like how it performs. U have done well.

Changed out the air variable for 3 1N4001 and a 100K audio taper pot. It is unbelievable to me the performance of such a simple receiver. All of the parts (count 35) would likely be in most folks junk box. And if not, the total parts cost can't be much more than $10. And, I could very well imagine using it for CW QSO on 40M.

Viz. www.goldmine-elec-products.com<http://www.goldmine-elec-products.com>

Then search item # G-21712 to reveal a lot of "over 1,000 resistors...almost all are carbon composition..."

Price is $20.00.

My experience with these people has been that their product statements are truthful; their post charges a bit lofty, and, more importantly the "good stuff" gets snapped up quickly enough so as to cause disappointment (me included).

I suppose a possible caveat is that carbon composition resistors age badly (only a bit like me), but that seems only to be the case if they are in circuit, an extended active duty tour, if you will.

Charles

From: kj6ix@...
Topic: 27378 Message: 27378

Greetings

I'm working on a Ten-Tec 1254 and I'm having problems. When I place a signal (9Mhz) from my signal generator to the antenna input I show a nice clean signal at the input to FL2. What hear on the audio output speaker is tone plus a lot of scratching type static. When I cut the foil at the output of FL2 I show a clean signal there. Now the audio is clean with no static type noise when I place a audio signal at the input to pin 6 of U9.
Any ideas anyone ?

Dale KJ6IX

Hello Dale,

I found the manual - (2 actually) but the resolution is poor, and I can't identify U9.
With imagination, I can identify FL2.

Can you suggest a place where I can find a circuit I can see more easily?

You description of the noise in the speaker is exactly that - noise.
It can come from resistor, capacitor (often electrolytic) or transistor.

However, I guess that you U9 is close to FL2 (or even directly connected to FL2, and (if that is so) this hints at the filter itself. (But remember - this is merely a wild guess based on my "guess" about your troubleshooting ability. Don't be misled! I may be wrong!!)

Can anyone point to legible circuit?

Les

Gary wrote:

> I use a regen for regular cw communications.

Although I sometimes sub in commercial receivers (Yaesu FR-101S rescued from junk, Drake R-4A "for parts or not working") for a spell, the receiver at W9BRD is usually homemade, and if it is it usually uses a regenerative detector. The regen-based receivers include two detector-at-signal-frequency tuners (one at 80m with a 5686 Hartley detector and the other at 40m with a synthetic-tetrode triode-connected-6AK6s detector, both based on the circuit at http://dpnwritings.nfshost.com/ej/wr/ http://dpnwritings.nfshost.com/ej/wr/) and two detector-at-IF receivers (one an 80/40 band-imaging job with solid-state local oscillator, diode-ring mixer, two-2N3904s post-mixer amplifier and a 12A6 Hartley detector at 1843 kHz and the other a crystal-controlled-front-end 80/40/30m job with a 12A6 Hartley detector operating at 3023 kHz +/- a few kilohertz for tuning around). Photos of some of these receivers (and the 7060-12A6 AF amplifier/filter box that amplifies their audo to headphone/speaker level) are available at http://dpnwritings.nfshost.com/ej/pictures/ http://dpnwritings.nfshost.com/ej/pictures/ .

BTW, a regenerative detector protected by good AGC is a fine thing. I've experimentally moved my 80-meter regen down to 3180 kHz and fed it with the (heavily AGCed) IF output of the FR-101S, and it worked just fine.

The only non-regen homemade receivers at W9BRD include an NE602-based direct-conversion detector in my Summer40Winter80 station-in-a-box contraption, and the 2N3904s-differential-amplifier-as-mixer 40m job that shares a pencil tin and a Twix box with my 40m detector-at-signal receiver (http://dpnwritings.nfshost.com/ej/pictures/pictures3.htm http://dpnwritings.nfshost.com/ej/pictures/pictures3.htm). Since those pictures were snapped I added a second dual-gang cap (in the right-hand Twix box) to give both receivers a fine-tuning control, and expanded the tuning range of both to cover 7000-7125 kHz.

All of these homemade receivers are entirely suitable for two-way communications work. That's why I built them!

Best regards,

Dave

As an example of this, when I worked Don just ahead of 9 AM ET near 7050 kHz this past Sunday, the receiver of choice was the BG-5 80/40 band-imaging job (Hartley regenerative detector at 1843 kHz). That was my first contact using a newly recapped and tweaked Drake 2-NT; Don was using a _homemade_ vintage transmitter with a great authentic sound.

Ham radio healthily, happily and enjoyably proceeds _without_ kilobuck techno-porn computerized lightboxes.

The air variable takes up a lot of space. So I decided to put tuning diodes onto the circuit board. I'll take a picture soon and post it. If someone wanted to build one of these with readily available parts, the diodes of course are the way to go.

Tuning is just the same as with the air variable.

And what a privilage to work you David. I have been playing with a longfellow of my own concoction. Five 25L6 tubes bought for $5 each NOS , some maple straping , an old ceramic trimmer cap and a handful of parts.. PSU is what we call here AC/DC or transformerless and fits nicely on the bottom out of site. Two crystals in the socket selectable by a DTSP switch. I built this in "just for fun" style without a schematic just using circuits I am familiar with. From the moment I plugged it in it has been doing a decent job for me and I have gotten to really enjoy using it. It is still morphing. For instance today I will try different screen voltage as I suspect I may be low however I am already ready to turn it back to original if my guesses prove wrong. I have also built a 20M one which is about 70% done as well as a 7 pin miniature tube version aka "The Pigmy". It just needs the tank circuit made for the output and it will be smoke tested. For the longfellow I would like to build the old superhet design which was essentially a 1700kc normal regen with a 80M/40M converter in front. I have a set of 1931 Grimes IF cans (round ones with screw on lids.) and It is my understanding they should be the right ones. It will also be transformerless with either 50L6 or 25L6 tubes . Reason? There is no reason. just company policy ;>)
Here is the one I used to work Dave yesterday. Would like to log you all. Actual freq is about 7052kcs using my favourite rock.

Might I speak a moment on the variable cap addiction.
For me finding them is a struggle. I know I could buy new but in retirement buy is a word one should not use too freely. Lately I have built several rigs with slug tuning and fixed cap. Both TX and Regens .I have been suprised at the results. It works very well and gives a level of control of tuning I had not experienced before. The space it saves is also remarkable.

Thanks Les

During my trouble shooting I had cut the foil between FL-2 (455khz filter) and U9 pin-6 (1st IF Amp) this did isolate the two ckts. I was able to see signals using a scope on the output of FL-2 which tells me this portion of the ckts was working. My audio was working again with no input from FL-2. I did inject a source at pin 6 and I had great audio no distortion. I did couple these two ckts with a .1 uf cap. and things start working ! great to hear station again ! but why ? I have been listening to stations all day and it has been working great.

The next problem is were to buy replacement parts ? such the volume control 10k audio pot ? the pot is 1/2 square. Those pots that Ten-Tec used in this kit suck ! I did mange to damage it.

A PTO is certainly FB. All of my old Ten Tec and Drake gear use them. Applaud anyone capable of building them. I guess they are easily constructed by those with abilities I don't have. A 50 cent pot and several 10 cent diodes (if not already in the junk box) is easy for me. The main reason originally used the air variable is it didn't require adding pads to the board and found it before finding the diodes here.

Originally bought some air variables intending to clone a Paraset. Still looking for the round "toit".

My comment was a bit tongue-in-cheek, Don.
Almost all my bits are scavanged or inherited.

I just happen to have a wee hoard of venerable variables
from my SK dad and an SK neighbour, which I, too, could not
consider purchasing. I would esconce polycons, but love slug-tuning,
and have scavenged worm-drive pots from old TV tuners and will
reverently use them with worthy Si diodes or varactor diodes one day!

I have decided not to post a jpg of the boat-anchor-style
variable C salvaged from an ancient VFO. It is as big
and heavy and as magnificent as its mechanics...

I posted a picture of the latest evolution of my 7.16 regen in KB5JO album. The three 3001 diodes are visible on one edge, and a dip socket holding the resonator on the other edge. I plan to buy some different frequency resonators to listen on the phone portion of 40M.

The circuit is the same as the original, just use three diodes for tuning instead of the air variable.

That's a classic -- love the finished slat-board construction, complete with side pieces. (The Longfeller was the subtitle name of "A Beginner's Two-Stage Transmitter" on page July 1946 _QST_, a 6V6-6L6 Boosted Pierce variation on Dana Bacon's "A Versatile Portable-Emergency Transmitter" on page 9 of July 1941 _QST_, You could build the Longfeller in metal or wood, and I bet more built it in wood than metal.)

> From the moment I plugged it in it has been doing a decent job for me and I have gotten to really enjoy using it. It is still morphing. For instance today I will try different screen voltage as I suspect I may be low however I am already ready to turn it back to original if my guesses prove wrong.

I like your choice of the 25L6. It's good for series-heater-string operation -- 5 x 25L6s = the magic number of 125 V for transformerless heating from the line _and_ it's available NOS pretty cheaply even today, probably because they were used in the hundreds as relay or solenoid drivers in early computers.

> From the moment I plugged it in it has been doing a decent job for me and I have gotten to really enjoy using it. It is still morphing. For instance today I will try different screen voltage as I suspect I may be low however I am already ready to turn it back to original if my guesses prove wrong.

Just go easier on the 25L6 screens than you might with a 6L6: 125 V max, 1.25 W max dissipation. The 12L6, 25L6 and 50L6 (and 6W6/12W6/25W6, the same tube rated for vertical-amplifier service) are the same tube with changed-up heater supply (35L6 pretty similar but a bit different), whereas Tuffy 6L6 was the king of AF power tubes and needed up to 250 V on its screen to put out max power at its max plate voltage.

What equivalent tube are you using in the Pygmy? 25B5/C5 or such?

> Would like to log you all. Actual freq is about 7052kcs using my favourite rock.

By my dial you were right there on 7052. I was using a "7050" rock that depending on the transmitter I use puts me somewhere between 7049 and 7049-1/2. Let's keep this action going -- I know that Gary, WD4NKA, has a rock around 7045 or 7047 if memory serves.

What was the receiver for that contact, Don? One of your TwinPlexes? (To those who wonder about the value of regens for two-way work, assuming Don was using a regen, regenerative detectors were used on _both_ sides of this VE3LYX-W9BRD contact (which started with me answering Don's CQ, BTW), with a band-imaging 80/40 superhet-regen with its 12A6 Hartley detector at 1750 kHz in play at W9BRD. [Have been saying "1843 kHz" across a few contacts, but I remember now that once I realized that I didn't care about harmonics of the set's oscillating 1750-kHz detector making weak band-edge markers at 3500 and 7000, I moved it

down to 1750 kHz, and there it stays. It's not a bug, it's a feature! Besides, a detector right on 1700 may suffer interference from an Expanded Band AM station or two if one is close enough as the crow flies.] I also knew that because Don (a) was probably using a regen and (b) is well-versed in The Way Of Crystal Control that he'd hear me even though my signal was nearly 3 kHz away. Users of modern transceivers tend to wear the selectivity equivalent of blinders and rarely tune up and down for replies, whereas with wide regen selectivity one gets panoramic reception for free!)

You faded out before we could get past the initial exchange--the Sun has been pretty hard on 40-m propagation for the past several weeks, and I've had several contacts wherein my correspondent has gone from S7 or S8 to in the noise inside of a minute--but that was maximum fun for a minimal contact, for sure. Next time I'll probably have a homemade transmitter on line--maybe my four-12AQ5s-in-parallel 25-watter or the two-12A6s-in-parallel (or single 12L6/12W6GT) Morning 40 with its ether-busting 8 W out!

Best regards,

Dave

I was preoccupied with the rig so had an old HR10 running with its speaker rather ten wear the phones and was listening using the beverage antenna . No reason why I couldnt have been using a regen. Two are with arms reach from where I was sitting. But you caught me superhetting.
I was aiming for screen voltage around 90 to 100. I got it to 84 and since it was working real nice I am going to leave it there. It has good manners, is drawing what I think is the proper plate current and sounds decent. I have elected to invoke "The Cabbage Rule" (Quit while you're a head)and leave it be. I used the stain I had left over from one of my home made fiddles. I seemed to suit the wood. This rig turned out better then I thought. I can rig the bell on the RBN at quite often. For years I never could so something about this rig suits the skimmer perhaps. I have the original article in the 1948 ARRL handbook. I followed the osc loosely but built the 4 tube PA from the heart. I tried a lot of different keying methods but settled on this one.Old Reliable I guess(All cathodes or B neg keying)
The Pigmy is almost done. I used a 6be6 for the osc and I had four 6aq5s so they became the PA. This one will have to use the bench PA so will be running with about 280 B volts coming in although I like to go easy on my osc . Pushing your osc too hard is like watching your Mom shovel snow. Not a good idea.
I have played with several 50l6 (and 50c6) rigs I made. I have a bare essentials which I built 50l6 but now has a 50c6. My first transceiver project was two 6sn7s and two 50L6 tubes. I replaced them with a 6l6 in the Rf PA and a 6v6 in the audio PA. And yes it is a regen , single control dual variable cap. It is an AM transmitter screen modulated and basically the Powerhouse regen build for the Regen. I have several 6L6 transmitters (about 30 tx s here and about 70% of them homebrew) I like best the 6L6 EH tall boy . BUT would like to try a KT88 someday.
Yes the band dropped out. You were banging in here super and then "poof" you was gone! Soon winter conditions will be here and we can play all day.
Very much enjoyed the QSO.

You can indeed get the little black steel wrinkle finish box. With a couple of caveats: (1) the box may be made from aluminum instead of steel (2) you might have to paint it yourself, but don't worry, spray cans of wrinkle paint have improved over the years, and work pretty well - assuming you follow the directions.

I had the XYL get me a Black square file box. I built a rig inside of it but I am not happy with the rig so itis getting a redisign. The box is good though however I really like wooden radios. And the shock hazard factor becomes very low unless you hunt for a bad place to put your fingers.

I like the valve-socket slot. Neat idea, even in metal -
especially if you don't have a hole-punch.

And surely, although we know we should disconnect the HT and
discharge any big capacitors, we will all occasionally succeed in
finding a bad place for our fingers when turning the chassis over :-)

Don wrote:

> I followed the osc loosely but built the 4 tube PA from the heart. I tried a lot of different keying methods but settled on this one.Old Reliable I guess(All cathodes or B neg keying)

Yes, the original Hadlock circuit had us keying just the amplifier screen--can't have one side of the key grounded then, and there's quite a backwave.

The 6BE6 is a good oscillator-tube choice because of its high transconductance, making it go easy on the crystal and getting the most out of sluggish ones. Sticking just to triodes, I found with my Novice Rig Roundup Boosted Pierce (http://dpnwritings.nfshost.com/ej/pictures/pictures4.htm http://dpnwritings.nfshost.com/ej/pictures/pictures4.htm) that a 6AB4 (half of a 12AT7) gave a much better note and less crystal stress than the traditional half-of-a-12AU7 6C4 in that position.

Cathode keying is just "cutoff voltage keying," and that'll be only a few tens of volts (for the final amp at least) with tetrode-connected 25L6s. But if we key the cathode _and the grid leak_, then it's B-minus keying and the full supply voltage awaits us at the key! (And we endanger the tube's heater-to-cathode insulation if the heater return is connected to common.) When my dad spruced up a Lettine 240 (6L6 oscillator, 807 final) to serve as my Novice rig he built in that all-RC differential-keying circuit from the keying chapter of a late-1960s ARRL Handbook. Unbeknownst to both of us, that circuit uses cathode keying for the final but B-minus keying for the oscillator, and since they were both keyed on the same wire, I had quite the wake-up jolt on trying to tighten the key connections during a particular sleepy late-night session on 80 meters!

> I have a bare essentials which I built 50l6 but now has a 50c6.

I built a Bare Essentials transmitter into a metal index-card box at age 15 or so and never ended up putting it on the air. As I was testing it on the bench, the next-door neighbors knocked on the back door and complained about sudden, intense TV interference. Sure enough, one more quick test found that even with the thing feeding just a light bulb load, every time I pressed the key Channel 2 went bright-white herringbone. I had built a very nice VHF junk generator (and was decades away from understanding the cause and its cure--a 47- or 100-ohm stopper resistor between the tube's screen and/or plate pins and the outside world would have fixed it handily).

Now I'm thinking about building a QRP Longfeller with 6AN5s...another computer tube. Wire the sockets right and I think 6AQ5s will sub right in with no other changes. Hmm...

Best regards,

Dave

When I keyed the screens I put a very high value resistor to ground on Key up. Not enough to bother power but enough to give the screens a definate place to park. What annoyed me was the osc always running. So I put a switch in to kill that and then said to my self. "self, this is silly. you know how to cathode key. Quite fooling around. I between I tried keying only the PA cathodes and a couple for other adventures. My first few contacts were though, with Screen keying. I have had good luck with my bare essentials rig. I often use it still. I must have gotten lucky. No complaints so far. It is in the mud room about 10 feet from the XYLs TV . She knows when I turn the linear on and am off tune. Anyway it is what I use the twinplex with.
Finished wiring the Pigmy this morning. Need to double check it and then work up the nerve for smoke test. That sometimes takes me a day or so.
Anyway Building as many of us know is fun.
Got to do some outside work now but later in the day I will be beating again on the Longfellow.

27403. OT: Heathkit HD-1250 dipper circuit

Yahoo group: regenrx (2016 — 2017)
Date: 2016-11-01 18:32:29 UTC
From: Hubert Miller
Topic: 27403 Message: 27403

I posted on regenrx some description of Heathkit dip meter HD-1250 circuit. Specifically the oscillator-buffer and detector circuit.
The buffer is a MOSFET with outputs taken from drain *and source* to (hot carrier) diodes whose outputs are joined. This per
the Heath manual description is a fullwave detector due to out-of-phase outputs to the two diodes. However David Newkirk
astutely pointed out that the driving gate of the MOSFET goes to ground, so the source-to-diode output is actually a source-
follower with an output of <1.
I said i thought the gate should have been returned to the source so you have out of phase outputs without the source output
being a source follower. I bought the manual just to read what Heath said and as i sort of feared, Heath said very little except
their high-level overall circuit description.
I hate to think it, but it looks to me like Heathkit's engineers made a mistake here. But it works "good enough" to do the job
even if it functions not as described. I recently passed up an Ebay offering of a HD-1250; i was thinking of getting one just to
experiment with moving a part around to "correct" the circuit, but i realized i do NOT need another project right now. Maybe
i'll just add it to the list of circuits to 'eventually' breadboard and look at.
Manufacturers do make mistakes. Of course, they have to put out a project on a timeline that eats money as time expires;
unlike us who can put a project aside and pick it up later to try to optimize it. It comes to mind an example Rob (another
Rob) posted a while back on regenrx about the Knight Kit Spanmaster receiver. One coil had been oriented on the chassis
so it sucked out signals at one area of the tuning range of a different band.
Comments invited.

It's a source follower in both cases. Returning Gate 1 to source or two a tap between common and source would merely change the dc bias level on Gate 1. I was pointing out that equal source and drain Rs does not necessarily result in equal source and drain outputs across equal impedances.

I also think that, as implemented, the overall circuit does operate as full-wave detector, but (I think, without subjecting the gain of both paths to more rigorous analysis) just with somewhat unequal drive across signal polarities. Assuming that the drive from the source-follower path is enough to push the associated diode into conduction--which it likely is [esp with hot-carrier diodes at work] or Heath wouldn't've done it-- the result would likely provide more net AF output than just a half-wave detector driven from the MOSFET drain.

BTW, we likely run into a dead end if we go on to ask, rhetorically, "But wouldn't operating the drain at a much higher impedance give more output with a half-wave detector than the low-Z full-wave detector?" because the detector is expected to provide useful output across the very large frequency span covered by the dipper oscillator. Operating the buffer/amplifier-MOSFET drain at a significantly higher impedance with the aim of driving the drain diode harder for more output would run into diminishing returns with rising frequency as a result of gain rolloff through net shunt capacitance. Tuning the drain to resonance could maximize signal at the drain, but only at a spot frequency. leading to a dipper with two tuning controls! :-) ("Tuning out stray capacitance" by means of resonance is one of the pillars of radio technique; patent wars [look up "four sevens patent" and "patent 7777"] were early fought over monetizing its benefits.) So I think Heath's approach here is a practical tradeoff between gain/output and instrument frequency response.

Dear amigos !

I am very interested in obtaining the circuit diagram of your Grid Dip Meter with a FET and a LED..., because high sensitivity D'Arsonval movement meters are not found locally...

It would be a very nice option for Cuban hams that are enjoying home brewing equipment but do not have access to instruments... Locally you can buy a digital multimeter (although very expensive) and build your own signal generator...

Please reply , if possible with circuit diagram to

First I see I said light goes "on" ? No the Light or LED goes out. I think the circuit overloads and dies on resonance but it is very pronounced. Nothing iffy about it. The light just winks out and right back on if you go by. I 'll do a photo and I hope I still have schematic for it. I started with one from online but morphed it do do my own. I built mine for 3 to 8 mcs. Used a transistor radio poly variable to tune it. Built it in a wood box. Don't laugh when you see it. Just know it works and was used on all the rigs I have built since spring. No plug in coils. No wrestling with cables, no warm up. I know I have the schematic here somewhere and I was sure i already had a photo but can't see it. I will make another in the morning.

If the gate is returned to the source, the drain circuit is no longer common to the gate circuit (via the formerly shared source to ground resistor.) It is no longer a common-drain circuit = no longer a follower circuit. But as you point out, the bias is upset as the gate is now zero bias.

SELF IMPOSED AND VERY EFFECTIVE RULES FOR BUILDING RADIOS AND ACCESORIES !!!

They are very logical and save a lot of time... Plus give you flexibility on parts values. For example, I , out of necessity, need to remove parts from circuit boards... many times add , with a lot of patience, extensions to the short leads, test them and place them on the glass jars that are my storage bins.... Following Don's VE3LYX logic, anytime I need to repair equipment or build something out of the blue... the preferred values list works wonders... A reminder: Even brand new, or NOS parts MUST be tested before using them for a repair job or a new project.... After a bit more than sixty years of tinkering with electronics, I can tell you several anecdotes about defective components going into a repair job or into a new project and finding it extremely difficult to detect !!!

27419. Crystal filters 2215 kHz

Yahoo group: regenrx (2016 — 2017)
Date: 2016-11-02 17:55:56 UTC
From: Hubert Miller
Topic: 27419 Message: 27419

Anyone here been (realistically, not just daydreams for the future) moving forward with plans on a homebrew receiver with an IF of around 2 MHz ?

Reason i ask, i am disassembling a large instrument and i find myself with two 2215 kHz crystal filters, 3 kHz and 250 Hz. I have the SSB crystals for it too
but their freqs make for a very tight SSB bandpass. I have the boards pulled and i can supply schematics with this.

The instrument is a Sierra 128 Frequency Selective Voltmeter. Its sin was just that it is so darn large. As large and heavy as a Hammarlund SP-600 but
not quite as useful. Before i started in with the scalpel i did check it out. It was interesting seeing that WWV was delivering 10 uV from a 3 foot wire
into 600 ohms BUT there are much more compact units out there if you need this capability. I sold 2 of them at Puyallup hamfest for a price so low
i regret it now. The unit is the easiest to take apart equipment i have ever processed. Unlike consumer electronics, it's not built sandwich style and
no insects, dirt etc. inside. The tuning caps are very high quality with strong plates. The power supply came out on one board, complete. Now i wish
i'd kept the other 2 i had an processed them myself. I got the strong feeling the buyer didn't really know what they were, but that was okay with me,
his money was green. Oh yeah, get this, there's a complete board with 100 kHz osc and harmonic generator. The transistors are socketed so that
really kind of dates it.
Now i also have a 19 inch rack cabinet with space 10.5 inches tall. I don't know whether this size is useful to anyone and worth dragging to a
hamfest, or should i just take it to the metal recycle?

Bet those filters came from Blackhawk Engineering of Janesville, WI. 2215 was used as the first IF in one or more of the NC-30x receivers, and Goodman used a pair in his "What's Wrong with Our Present Receivers?" experimental front end in 1957 QST and later in his "Miser's Dream" receiver of 1965. (Of which, as a result of having had low friends in high places I happen to have the full, never-published-in-QST schematic available at http://dpnwritings.nfshost.com/ej/misers_dream/

Yes, you nailed it exactly. I think there must be VERY few people in our six billions who could name this part.
Thanks for the additional info!
The ‘Miser’s Dream’ looks like a smart design, and i think it maybe outperformed many of the higher priced
factory built receivers out there. The filter matching and switching details the schematic provides may prove
very useful to the next owner of these filters, so it was good to see that too.
Would have been a fun and very capable DX machine to use.
Was this circuit actually built, and if so, do you think the original survives?

Mike wrote:

> There's that infamous floating diode product detector again. Any comments? Was it actually tested in the "Miser's Dream"?

Yes. Here's what By had to say about it:

"The product-detector circuit is an adaptation of one devised by Don Norgaard ("Single Sideband Reception," _G.E. Ham News_, November-December 1948). In the original with 6H6 twin diodes it looked complicated, but with two germanium diodes (and their finite back resistance used for d.c. returns) it becomes quite simple. With about 6 volts peak b.f.o. voltage and a maximum signal of about 0.1 volt, low-distortion demodulation is assured.<Paragraph>(In a subsequent article ("Signal Slicer," _G.E. Ham News, July-August 1951) Norgaard mentioned that the semiconductor version would be noisy, and that is indeed the case. However, at this point in the circuit the noise is of no consequence, since amplified it only comes up to about the hum level of the set. Hum and detector noise are both masked by amplified background noise.)"

Cool about the subsequent invention and rise of this thing called the In-ter-net is that we may can now directly also access those G.E. Ham News issues via the page at http://n4trb.com/AmateurRadio/GE_HamNews/ge_ham_news.htm http://n4trb.com/AmateurRadio/GE_HamNews/ge_ham_news.htm . You have to hunt through the 1951 issue for Norgaard's comments about germanium-diode-detector noise (it's not in the Slicer article itself).

I will say this about solid-state-device noise, one perhaps not directly related to the noise-resistance-based discussion about germanium diodes replacing 6H6s/6AL5s. Modern AF power amps intended for reproduction of high-dynamic-range digital audio are very quiet, of course, but are commonly not available in packages I can deal with without a jeweler's loupe. And anyway beginning in the late 1970s I adopted the LM38x series AF amps as constructional buddies--they're oh-so-easy to uses as along as you pay attention to layout, ground loops, and power-supply decoupling. But even the best of them is disappointingly noisy, even when configured for minimal gain (not 46 dB, thanks) compared to a garden-variety beam-power-tube AF power stage. My 7060 (triode-pentod)-12A6 (beam power tube) AF utility amplifier is _so quiet_ compared to single-IC solutions that predate the digital-AF age that I keep not building an LM380 equivalent even though I have a sleeveful of the guys.

BTW, fun fact about the 12A6 at W9BRD: Although I do admit to having "a thing" for them, I surprised myself recently by realizing that I now have active projects that use them well in quite a broad range of applications: AF power amplifier (of course; AF filter/amp box); 2N7000-switched mixer (BGCD Regenerodyne); Hartley detector at IF (BGCD and BG-5 Regenerodynes and BRD-160 regen); RF power amplifier (Morning 40 transmitter; puts out 8 to 9 W with a single 12L6GT or two 12A6s in parallel [metal tubes neutralize like a dream compared to glass, though); and--because I was too lazy to spend another 1.5 min searching for one of my 12SJ7s and had 12A6s on the bench--AF voltage amplifier in BRDd-160 160-m

regen. The only 12A6 role missing from active service is "crystal oscillator," and I have a Boosted Pierce in the works that will add that one to the stable (as well as trying out the likes of the 6AN5, 8106, 6AQ5, 8156 and maybe even 7984)!

Best regards,

Dave

Ed wrote:

> Then again, a lot of beam tetrodes will work for that purpose without much effort, as long as you put some effort into properly loading them.

True, but in the 12A6 several useful factors come together:

1 It's metal (I have seen later, 12A6GT variants) and therefore inherently well-shielded with Pin 1 connected to common

2 It's heated at 12.6 V, and therefore its heater can be straightforwardly operated directly from fixed-voltage dc supplies commonly available today

3 Along with only three other tubes that I know of (14A5, 7701 and 5686, its direct equivalents by design) it has the lowest heater power (circa 1.9 W) among North American beam power tubes, an important factor in keeping down frequency drift across receiver warm-up

4 It is readily available cheaply, apparently having evaded being considered useful by the "tube audio sounds better, even for program sources that have otherwise entirely solid-state and digital for decades" believers

The warm-up-drift issue is real-world as soon as you want to use a regen for two-way work. I had some fun a few years ago playing with various dual/double triodes as synthetic-tetrode detectors, in particular the 13DE7 dissimilar dual triode (which heats perfectly well at 12.6-ish volts). But the xDE7 takes over 5.6 W to heat, and in the medium-sized enclosure I was using at the time for a test bed, all that heat kept the receiver drifting for an hour or three even with the tuned-circuit components well-spaced from the tube. (I've found the 1631 [12.6 V 6L6] to be a perfectly good regenerative detector tube, for instance, but between its large size and its high heater power [as much as a 13DE7] it's impractical from a component-heating standpoint. I will say that the fact that so many octal power tubes share the 7S/7AC basing makes for fun swapping, say,1631 for a 12A6, and vice versa, in detector experiments. In only a few cases do we have that luxury with miniatures.)

BTW, there was a _premium_ 12A6--the 5659 (https://frank.pocnet.net/sheets/201/5/5659.pdf https://frank.pocnet.net/sheets/201/5/5659.pdf). Some years back I ordered one or two from a Florida concern that had that number in its online catalog and after a considerable delay received two nicely _faked_ 5659s with very, very fresh black paint and very, very fresh white markings _and_ a telltale "12A6" stamped into their base sleeves. (Pages like that at http://www.jacmusic.com/nos/images/Fakes/ http://www.jacmusic.com/nos/images/Fakes/ show up my new-black-and-silkscreened-white-paint genius as a mere piker. At least I was out for just mild adventure and not that Pot Of Golden Sound awaiting those who find the end of the rainbow to score the perfect "matched pair"--there any other kind of pair if you're buying tubes, even if they're pentagrid mixers or VR tubes?--of dual triodes with "black plates" and O/square/halo/whatever getters...

Best regards,

While receiving with a BJT infinite impedance detector T3 in my previous posting I noticed that the detector had some bad interaction with the Q-Multiplier stage, causing erratic regeneration control and even backlash when using an MV loopstick coil. When the Q-Multiplier goes into and out of oscillating, the impedance at the base of the infinite impedance detector stage rises due to the increasing DC voltage over the emitter resistor R9 of 100k by the rectifying action of C13. T3 is more biased to cut off, rising its input impedance which causes the Q-Multiplier stronger oscillating. SSB reception was also warbled and less intelligible.

Here I have inserted a detector diode D5 between T3 which is now a buffer stage and the AF preamp stage T4. R9 sets the right bias current through the diode. In this circuit the regeneration control is very smooth.

For L1 you can take an MW loopstick for receiving the MW Broadcast band, or a loop aerial for receiving shortwave. A ferrite loopstick kan also be used on shortwave, wind a coil of 7 turns onto the loopstick with a space of a few mm between the windings. You can also use a 10.7 MHz TOKO IF coil for L1, an aerial can be connected via a small capacitor of a few pF onto the top of the tank coil L1.

A very unusual regenerative receiver in which there is very much RF amplification between the regenerative stage and the detector stage. But beware the high frequency roll off at higher shortwave frequencies due to the Miller feedback capacitances between the collectors and the bases of the 2N3904s. And I think that this receiver will have much background noise due to the BJT RF amplifier stages between the regenerative stage and detector stage, the noise coming from the regenerative stage is also amplified. At http://americanradiohistory.com/Archive-Poptronics/90s/94/PE-1994-03.pdf http://americanradiohistory.com/Archive-Poptronics/90s/94/PE-1994-03.pdf you can read an article about the original Global Span receiver on pages 33-40.

Advantage of this receiver is that you only need single two terminal coils without coil taps or tickler windings, which makes band switching much easier.

A much simpler regenerative receiver with a differential pair Q-Multiplier (T1, T2) and a separated detector stage T3 with D2 is this one which also uses a two terminal coil.

I did a simulation of that rf amplifier. There are 4 stages, each of them amplifiies by 4.2 times or 12.5dB. Two stages are fixed with 25dB and two can be switched in. The amplification can be changed from 25dB to 37.5dB and finally to 50dB. The amplification drops to -3dB at 30MHz.

Some years ago i tried a similar setup with q-multilier, one rf-stage and a square law detector. This works very well for am reception. It behaves a little bit like a crystal detector, but with more selectivity and more sensitivity. The reception works already without going into oscillation.

All the sensitive detector circuits are showing a distortion between 5 and 10%, while receiving weak signals. To reduce the distortion, the detector diode or transistor has to be feeded by a signal as high as 300-500mV. Then the distortion can be reduced to 1% or below. IMO this is exactly, what this Global Span Receiver is doing, it is a "HiFi Regenerative Receiver".

> this receiver will have much background noise due to the BJT RF amplifier stages

I don't think, that this stages are doing any harm to the S/N ratio. They just amplify, what is already there.

Best regards,
Bernd

The best thing you can do, is using a cascode circuit between the regenerative stage and the detector stage, a cascode circuit has a much wider bandwidth than single BJT amplifier stages. An example of a cascode amplifier is this one below. Here it is also used as a Q-Multiplier which is followed by a full wave diode detector.

A dual-gate MOSFET, then. A dual-gate MOSFET is two single-gate MOSFETs in cascode. Just as, in effect, a vacuum screen-grid tube can be synthesized by two triodes (or a triode and a tetrode; whatever) in casode.

Thanks for the comments, I am finding that some of the silicon parts are now obsolete and hard to find. This means a lot postage since there will need to be several suppliers. It also dampens my enthusiasm.

I liked several of the features like the only connection to the front panel is DC, the frequency counter circuit, varactor tuning and the toroid coils.

If I continue it will be a modular approach, I might build up the RF amps and see how switching stages in and out works. I like the DC control audio amp circuit, I was trying to remember another audio out put IC that had that build in the IC features, I think I saw it in Sprat. Also will take a look at all the suggested links. thanks.

Topic: 27441 Message: 27441

I built a Twinplex, used it awhile, then converted it to a 2 tube regen from Aug 1951. I wasn't really happy with either one. Am looking for a circuit with an RF amplifier to isolate the antenna from the regeneration stage, and a regeneration stage using a Hartley oscillator. Ideally appropriate for common 12V filament tubes. I had converted the 1951 to 12V tubes, use my 13.8VDC supply for filaments and series connected 9VDC batteries for the plate supply. No hum.

Any circuit advice for this? I hope to use the existing chassis as a basis for 3 tube.

73, Curt KB5JO

Hello Curt,

You'll see many threads on the RegenRx list about "best receiver" - so I can only repeat advice already given.

First, James Millen gave the best advice regarding any set - build it like a battleship; pay attention to the dial mechanism and consider feeding the filaments with a regulated DC supply. (OK, that last point is more recent, but it's still good advice.) James Millen also makes a final observation - a well constructed set will operate fairly well, without regard to the circuit. This advice may not be so valid for a 3 or 4 tube set. Also, unless you're a purist, consider using 12 volt filament tubes and use a transistorized 12V AF system. You can pick up a complete AF module for a few dollars now.

Next, there is consensus that every added 'toob' gives a good improvement in performance - up to 4 tubes. After that you have to work harder for less benefit. You might expect a three 'toob' set will perform better than your two 'toob' set.

I can't give good advice without mentioning two specific technologies - the regenerodyne and the Jones Superhet. If your interests lie in the 80m-40m region, then consider a band imaging superhet. Arnie Coro speaks well about the performance of the pentode/Hartley detector. In his circuit a pot on the screen grid controls the regeneration by varying the SG voltage. Arnie's advice applies to a specific 'tube' - the 6AK5. I built 'my version' of Arnie's circuit, and his claim (I hope I don't misrepresent his words) - that the regeneration is 'silky smooth' - worked for me. Oh, no growling, no hysteresis and it uses readily available parts. My set is about the point of best adjustment when the SG voltage is between 10-15 volts. I follow Arnie's advice and run the detector supply at 36 volts. I suspect the circuit would perform well with anything up to 60 volts, but I haven't tried that. So I used a 6AK5,but I suspect a 6SJ7 or 6J7 will give good results. Less Gm than the miniature tube - but enough, I think.

When I say, 'my version' of Arnie's Hartley I mean I followed his formula closely, with only one change. David Newkirk writes about the advantage of the "hi-C" tank circuit on the detector. I don't follow that advice to the letter - DN recommends capacitive reactance values below 100 ohms. I chose about 125 ohms. But I don't think David will cane me too hard for this deviance! But David Newkirk's formula is based on sound maths. Try it - even if your detector uses a triode.

Recently Vlad 'N' presented a detector based on the Vackar configuration; I think this design is well worth trying - and I suggest as the detector in a regenerodyne. That's the good news. The bad news is that his circuit depends on a particular 'tube' - the 6AS6. There may be an octal tube that has dual control, like the 6AS6, but I don't know one.

When you chose a specific configuration I'm sure list-readers will offer suggestions that will help. Readers of this list have a lot of experience.

Good luck with your set.
Don't forget to build it like a battleship, using the quality components.

Hi Curt,

an excellent 3-tube regen is the circuit from the RCA tube manual:

http://www.w7ekb.com/glowbugs/rx/Regens/ACRegenRCA1.JPG

You will find a lot of additional information on the web.

There are more regenerative receivers which you can build with garden variety semiconductors, without worrying about certain semiconductors becoming obsolete. Like this one below which has a differential pair Q-Multiplier and a BJT infinite impedance detector preceded by a buffer stage.

It is a multiband regenerative receiver which runs on a supply voltage of 3 V. L1 can be a medium wave loopstick coil, or a small loop aerial on shortwave. You can also use a ferrite loopstick on shortwave, wind a coil of 7 turns on a ferrite loopstick, spacing between the windings is 2 mm. Advantage of this receiver is its use of simple two terminal coils without coil taps or feedback windings.

To go with my longfellow I am starting today on a regen superhet. It is kinda of a free build but will be basically an untuneable appr0x 1700kcs regen with an audio amp on the out side and a SW converter on the in. Tubes will be I plan 25l6 and two 50l6s so power can be stolen from the longfellow or a similar supply. Regen Coil is already made . This could go either way (good or disaster) but should be fun. Regen will be by pot control. Here's hoping ! I want a easy to use , loud enough to hear, matching rxx for my longfellow station.

Congratulations amigo Don for joining the happy users of the
Regenerodyne receiver circuit !

The 25L6 and 50L6 vacuum tubes work very well as a Hartley regenerative detector with screen grid voltage regeneration control. You do not need to run the detector plate voltage much higher than 50 volts (that is my top limit) and the screen grid control provides a very smooth transition towards self oscillation... It works so well that you can make the tube operate at the knife edge of the point where it will break into oscillation, becoming at that point a very sharp selectivity detector.... My typical 40 meters band beginners REGENERODYNE, uses a computer microprocessor clock frequency crystal of 4.000 megaHertz as the mixer injection frequency and the regenerative detector tunes from 3000 to 3200 or 3000 to 3150 kiloHertz for an excellent bandspread coverage. For a general purpose shortwave receiver, a different tuned circuit for the regenerative detector spans from 2 to 4 megaHertz, and using a 6.000 megaHertz crystal to cover from 8 to 10 megaHertz... By changing the crystals at the input converter, ¨a la Collins radio style¨ I can cover many 2.000 megaHertz wide segments of the short wave spectrum.

My only concern with the use of the 25L6 and 50L6 is that they will need to be provided with direct current for the tube's filaments in order to prevent the background HUM in the audio output....

One more note: The well built coil for the regenerative detector is a must and the same holds for a high quality variable tuning capacitor... In the case of your receiver, I see you plan to use a front end variable frequency converter that will require I highly stable VFO for mixing with the input signal.

Second note: All my experiments with vacuum tubes vs. solid state regeneratives show that the vacuum tubes versions are much easier to achieve good reception !!!

Dear amigos:

The selection of the tuning range for the regenerative detector of the REGENERODYNE involves the knowledge that 1.7 mHz is the lowest useable frequency, because it is now the top of the AM broadcast band... At night, the 1700 kiloHertz AM stations can leak into the detector !!! That is why after many experiments, I decided to use the lower frequency limit at 2.0 megaHertz that can be completed with a 3.5 megaHertz upper limit. Then your tuning range can provide a nice 1500 kiloHertz tuning range in an area of the radio spectrum that during daylight hours is essentially not used nowadays... At night some signals can leak into the detector stage, especially if it is not well shielded. The ZL2JJ receiver excellent mechanical and electrical construction prevents signals on the IF to enter the detector. Using the 1.8 megaHertz lower limit is a valid option that by a simple switching arrangement feeding the antenna directly to the regenerative detector adds the 160 meter band reception option... My 6AK5 Hartley regenerative detector sensitivity on 160 meters works very nicely indeed !!! But... by using the 2.0 megaHertz lower limit, the dial of the regenerative detector can be calibrated with 1500 units , that when using exact frequency crystals at the front end converter makes possible a very nice approximate frequency reading... Example, with the 5 megaHertz 5.000 crystal , the 2.000 low end tunes to 7.000 megaHertz !!! The 12000 kiloHertz computer clock crystal tunes from 14000 kiloHertz up to 15500 kiloHertz, bringing the 20 meters amateur band and the bonus of the still much in use 19 meters international broadcast band... Also, my front end crystals provide the ¨backward tuning option ¨ by subtracting instead of adding... Example 12000 kiloHertz crystal , minus 2000 kiloHertz (the low end of the regenerative detector) tunes your radio to 10000 kiloHertz , a frequency you can be certain by listening to WWV and WWVH... Then 12000 kiloHertz minus 3500 kiloHertz tunes to 8500 kiloHertz... BUT this option ¨tunes backwards¨ within the tuning range from 8500 kHz to 10000 kHz .

Now for more information about the still experimental VHF Lo-Band Regenerodyne... using computer TTL clock modules.... A 48 mHz module makes possible to build a nice 6 meters receiver... that tunes from 50.000 to 51500 kiloHertz !!! the radio is very stable and it can be used to monitor the 50.110 or 50.125 megaHertz 6 meters band calling frequencies...

Good point I hadn't considered! Using a crystal for the VFO makes for a easily-stable oscillator vs. using LC, and would simplify the project both mechanically and electrically. I think Don's planned "AC-DC" tube lineup is intriguing, guessing he'll need only a small transformer for B+. Looking forward to hearing how it sounds!

27462. Regenerative preselector with or without mixing

Yahoo group: regenrx (2016 — 2017)
Date: 2016-11-11 02:43:01 UTC
From: qrp.gaijin@...
Topic: 27462 Message: 27462

I'm investigating a (solid-state) regenerative preselector for a pocket-sized shortwave superhet project with IF=455 kHz. The regenerative preselector (i.e. RF Q multiplier) would, of course, always be operated below the oscillation threshold. I am considering two options:

1. Regenerative preselector without mixing, coupled into a self-oscillating mixer to produce the IF output from the self-oscillating mixer.

2. Regenerative preselector with mixing (e.g. http://www.qsl.net/wd4nka/TEXTS/qdynef.htm http://www.qsl.net/wd4nka/TEXTS/qdynef.htm), where the preselector itself also serves as the mixer, and a separate local oscillator is coupled into the regenerative preselector, to produce the IF output from the regenerative preselector.

For reasons of design minimalism I have chosen to use only two (and no more) active devices for the regenerative preselection and frequency conversion functions. So the mixing function has to be either moved into the local oscillator (option 1) or into the regenerative preselector (option 2).

Is there any reason to prefer one approach over the other? My intuition suggests that option 1 might produce lower IMD, as the regenerative preselector could be biased for linear amplification in this case, whereas option 2 requires (for the mixing action) that the regenerative preselector be biased non-linearly, which seems like it might introduce more IMD (trying to amplify and mix at the same time) and degrade the S/N ratio worse than option 1. On the other hand, even with option 1, the self-oscillating mixer will be prone to IMD as well, which might make options 1 and 2 actually about the same.

As this will be a portable receiver, I will use either a ferrite rod antenna (that has been confirmed to work well at shortwave frequencies) or a whip antenna. Therefore, signal levels will likely be small enough to prevent massive overload of the regenerative preselector stage. Still, I'd like to choose the best option for the front-end design, assuming there is any difference between the two above options.

Any opinions?

Thanks,

qrp.gaijin@yahoo.com
http://qrp-gaijin.blogspot.com http://qrp-gaijin.blogspot.com

P.S. As a side note, I would actually like to use only one active device that does regenerative preselection at RF, while simultaneously oscillating at the LO+IF frequency and mixing the two to produce the IF, but it's rather challenging to do all of this in one device -- though I've seen a one-transistor dual-frequency oscillator by AA1TJ that suggests my one-device idea may be feasible if the gain for the one of the oscillation paths is reduced to serve as Q-multiplication instead. However, it's then questionable whether such a one-transistor configuration could stably be tuned over a wide frequency range.

"50=50=25 = 125 volts"

That is true for the series heaters. HOWEVER, I seem to recall that you said the tubes were 50L6's and 25L6. IF that's the case, the HEATER CURRENT of the two tubes is different. If I recall my AA5 radios correctly, the 50L6 draws 150mA of heater current, and the 25L6 draws twice that, or 300mA. You'll have to put equalizing resistors across the 50L6 heater connections to to equalize the currents or everything will be wonky. . .

Perhaps , depends where I put the 25l6 in the chain I think. I have been down this road before with my transceiver originally had a pair of 50l6s (transmitter output and audio output) and a pair of 6sn7 s (regen detector and audio preamp as ell as reflex RFamp (gg) If I used 6sl7s which make a better regen I would occasionally lose one. Had I known that I live in a high voltage area (119 to 127) I could have used 12sl7 s or 12sn7s and probably would never have had a problem. Eventually i wanted more output then 50l6 could deliver and rewired it for 6 volt tubes adding a transformer. I still have it and have used it with in the last few months. So I have this idea that if I put the 25L6 at the end of the string the 50l6s wont know the difference as all they will see if 100 volts to share.. I also have some 50c6 tubes which i suspect draw heavier. so I could use them but I think my plan will work and I am willing to gamble a 8 dollar tube to find out. I always ask myself what is the worst that can happen. But you are right , It is not just hook up and go. You have to plan a bit. That is why God invented smoke.

Any way you look at it, if you wire the heaters of 2 50L6's and one 25L6 in series, without equalizing resistors across the 50L6 Heaters, you're going to get incorrect Voltage across all the heaters. The Voltage across the 50L6 tubes will be high and low across the 25L6. By how much I'd have to go into the math of it, but it gets a little complicated as straight Ohms law won't work, the heater resistance changes with applied Voltage/temperature.

Still the circuit may work, just not optimum.

My "Quick and Dirty" suggestion would be to use a 35L6 (if one is handy) instead of 25L6. The35L6 has a 150 MA heater like the 50L6. Yes, that adds up to 135V, so you'll be "starving" the heaters slightly, but it won't require any equalizing resistors.

I am just going to build it. Worry is not something I am big into . I doubt the 50l6s know that the 25l6 is a tube and not just a dropping resistor.

Dear amigos: In my high school days series connected filaments (heaters) were the rule in the lower cost TV sets (black and white of course)... Rare filament voltages led to tube designations as 3BN6, 5AT8 and the like... This was a cost saving trick... following the experience with the All American Five radios in the USA and the Phillips and Blaupunkt radios in Europe that used series connected heaters to avoid the expensive power transformers...

I remember having ¨done a conversion¨ of an ALL AMERICAN FIVE tabletop radio to using 6 volts filament tubes, connected to a small heater 6.3 volts transformer... Adding more filter capacitors and a filter choke too... both mods made the radio sound much better... running a 6AQ5 audio output.... No more burned 35W4's or 5OC5's HI HI !! My advice to using 50L6's in series is to include a series voltage dropping wirewound resistor if your line voltage is 120 volts.... and to run the 25L6 with its own separate voltage dropping resistor required to go from 120 to 25 volts ! By the way, both resistors will generate a lot of heat !!! AND, it will be a good idea to install a series connected special voltage dropping resistor made from a non linear material that will start with a high resistance and after heating up drop to a low resistance ... this anti surge devices are life savers for vacuum tube filaments !!!

120 to 25 volts ! By the way, both resistors will generate a lot of heat

My suggestion is to parallel the two 50L6, then put those in series with 25L6 so the heater string draws 300 mA at 75 volts. Then add a series diode to halve the power from the 120VAC line and drop the voltage down to effectively about 85VAC. (see attached schematic). I was taught this trick a few years ago and is my favorite to light odd-ball tubes without a heater transformer (or other higher-than-needed voltage). In this case the tube heaters will be overrun a bit, or a series resistor could be added to drop the extra 10 volts.

I haven't actually tried this in a regen so not sure how it would affect receiver performance.

Sorry this is a bit late coming . . . probably Don has his set built and playing by now :-)

No Don is thinking his way through it a bit at a time. Audio section is done. Regen section is about 3/4 done. and pierce osc is pretty well done. I try to do what comes clear to me. Then I invoke what I call The Cabbage Rule. Quit while you're ahead. Somehow when you do that the next step seems to sort itself out overnite. As to heater differences I am not that concerned and that does not mean I think those who are are wrong. It is I dont believe it is significant problem on an expermental junk box build. I could use all 35l6 and add a 6 volt audio preamp and everthing would be perfect and we would all be happy but right now I am more interested in exploring the design idea. The really neat thing about using 50l6 or 25l6 tubes etc is you can also use 6w6 6f6 6y6 6v6 6l6 12l6 35l6 simply by changing heater voltage and adding a transformer. Other then heater to parallel all other wiring stays the same. And I thought about it too. Even with the longfellow. ^a 6v6 osc and 4 6l6EH tall boys at 600 volts would be a fun rig too and would have some serious grunt. Anyway this is for me an intiquing adventure. I hope it turns out ok but time will tell. donVe3LYX

When I was in my teens my neighbour, Geoff D'Emden - VK7ZAS, introduced me to amateur radio.

Money was scare in those times, and I dared to suggest rectifying the mains to supply B+ voltages.
Geoff, who was always aware to the possibility of shock told me that no transformerless sets would be found in his shack.

So I built sets using a transformer. I discovered that the effort in finding (and wiring) a transformer was small compared with the effort needed to built a good set. I'm pleased Geoff took the time to speak to me about safe electrical practice.

Here in Australia, where electrical standards for safety are higher than USA, the use of transformer-less sets is discouraged COMPLETELY. While some may build death traps, their design should not be promoted on public lists such as Regenrx.

I just purchased, on Ebay, a pair of voltage converter modules. One is a buck converter and the other is a boost converter. I'm going to use them with a 12v battery (or bench supply) to make both 6.3v and 90-350v for tube fun. The cost of the supplies, as well as an aluminum chassis to hold them, was around $30.

The only thing to keep in mind would be to add filtering on the supplies. Switch mode supplies are noisy but the noise can be controlled.

Hello Ed,

(I'm off the main topic now - Regen superhet - so please excuse me.)

I have a 12V to B+ converter here - it's noisy. It makes a LOT of hash!
I want to use it with my regen detector.
At the moment I'm running +36V DC on the B+ line - according to Prof Coro's experience.
I'll have to find a way to filter the noise - and I'll be interested to hear (or read) your experience in filtering. I paid $10 for it. It will supply any voltage from +45V to +180V, at 5 watts, by changing the "program" resistor.

Les

Dear amigo Les and other list participants...

Having to deal with the challenge of suppressing the HASH, or more properly ¨ broadband noise¨ generated by switched mode power supplies is simply mind boggling ... to say the least.

The generation of zillions of harmonics by the sharp rise and fall of the switching waveform will send Monsieur Fourier to the mental health hospital !!! Harmonics and more harmonics of the main switching frequency are the culprits...

See... switched mode power supplies are now everywhere... and they have become a nightmare not only to us users of the radio spectrum but also to the power utility engineers that have to deal with the dreadful problem of power line waveform distortion caused by those devices !!!

Suppresing the RF hash coming from a 12V DC to B plus converter will prove to be very difficult, because you will need a lot of shielding with steel plate (aluminum boxes will not work) plus at the output you must install a very complex set of RF filters...

Even a simple cellphone battery charger can radiate around it enough RF hash to wipe out signals within a wide frequency range !

EL CHEAPO... that meaning very low cost poorly designed and also poorly assembled switched mode power supplies are a real headache for us radio hobby enthusiasts...

At my new workshop, top priority was given to proper ground connection, plus an AC power line filter that can handle 10 amperes... It took one of my star students quite some time to design the filter that is connected from the power company electric meter to the main workshop ¨operating table¨ where I will be doing soon all my electronic construction work... The same line , provided with additional filtering goes to the adjacent table where my ham radio station will be located....

Finally , my advice... if you want your vacuum tube regenerative receiver to work properly feed it with very well filtered direct current coming from a linear power supply , with the transformer provided with an extra Faraday shield between primary and secondary... high capacity good quality low ESR electrolytics and a well built filter choke will do a great job...and do not forget to include transient suppressors as the input to the power transformer , plus high quality .1 mfd at 600 volts bypass capacitors from each side of the power line to ground....

73 and DX

Arnie Coro CO2KK

P.S. Las evening propagation conditions on the 80 and 40 meter bands
were really poor... the worst in a long time... so bad that I thought
the three radios used to test the propagation from 5 to 10 megaHertz at
my local midnight 0500 UTC were all broken down >!!!

Dear amigo Les:

My heartfelt congratulations for your posting about the danger of using B plus provided by directly feeding rectifiers without the use of isolation transformers...

Having received not one but many electric shocks when as a teenager I was helping at a TV repair shop that also catered for radios... I soon learned to install at my little table assigned to me by the owner of the shop, a beautiful 300 Watts capacity one to one isolation transformer, and also a VARIAC with a current capacity of 5 amperes and a voltage range from 0 to 240 volts AC... From those early practical learning days while attending engineering school, I have preserved the practice of using power line isolation via a one to one ratio transformer, a low impedance ground, and also the use of fast acting overcurrent protection... PLUS, a BIG knife switch at the wall marked MAIN SWITCH , so that all power may be cut if someone gets trapped by electricity .... in spanish ¨ INTERRUPTOR GENERAL ¨ that mean main switch...

I'm with you, Don. I grew up with AC/DC stuff and I learned early on where the high voltages were. If anyone is prone to blindly grabbing wires and is worried about electrocution, perhaps they should take up a different hobby. Even a transformer powered set has "hot" power leads running through it to the switch and primary winding. I've been zapped more often on these sets that on AC/DC sets.

Yes. The only difference between ac/dc and a transformer is the magnitude of short-circuit current. If you short the ac line the house system can supply several hundred to several thousand amps and you get a big spark. Short a transformer and the current is limited by the size and impedance of the transformer to a few amps, and not much spark. This is a distinction without a difference as it only takes a milliamperes to kill you. One can argue that ac/dc is safer because the voltages are lower. The only real hazard is the hot chassis problem, and with polarized plugs it goes away.

Hello Don,

I'm more interested in progress with your minimalist superhet than how YOU build YOUR set. Your set will be mainly used by you, and your personal safety is YOUR responsibility. At the same time we all have a responsibility for those around us - remember the parable about the Samaritan and 'neighbour' - and I AM worried about the High School Student who thinks, "Don's gear was transformer-less. I'll copy him." (Especially if the hypothetical student is reading this list and not in YOUR workshop, Don! I'm certain YOU would instruct him (or her) about safety IN YOUR WORKSHOP. But remember my experience - I got a wild-eyed idea about transformer-less power supplies from a book; and it was the personal instruction by Geoff, VK7ZAS - who warned me not to try about this dangerous idea.

I've always had an interest in regen. superhets (whether regenerodyne or the more common "Jones" superhet). and the idea of using beam tetrodes (such as the 12A6/6V6/25L6 (and so on) is very interesting for me.

Returning to your question, Do I know anyone who died from touching a live radio chassis? - no. Ross Hull was electrocuted in the 30s, but he got caught up with the EHT supply in a TV set. The figures give an electrocution rate (for USA) of about 3 deaths by electrocution per million. It's interesting that the death rate in Australia mirrors that in the USA. (I mean death by electrocution.) Over a decade the Australian death rate reported in the coroner's court was 321 persons. So - if I know a million people, only three will die by electrocution - and those mostly from sticking a knife in an electric toaster. But if some-one that I knew died from working on a transformer-less set and I could have saved that life - I wouldn't sleep for weeks, with that knowledge. I would never forgive myself.

About 15% of all deaths (in Australia) over the last decade were due to "low voltage" - and here that is under 600 volts. I read that one safety authority stated: "Remember that your body conducts electrical current, and that an electric shock of 120 volts can often be just as deadly as 600 or more volts."

I DO know that in one very rare case there was a fatality with extra-low voltage. (This is a voltage below 42V. In that case the current found a path in a wound - a cut - that by-passed the (higher resistance) skin and some mA found a path across the chest (and heart). That was a very rare accident - but still a fatality. From EXTRA-low voltage!!

48% of all deaths (by electrocution) in Australia are caused by a failure to follow safe working practise.

I have a nice S-38 (transformer-less) receiver. Ignoring the fact I can't connect this directly to the mains (we run 240V, not 120V) consider this: I got this set came WITHOUT a bakelite knob on the BFO pitch control. If I put an ALUMINIUM knob on this set, it would be a death trap (in USA) simply by reversing the mains plug orientation in the wall. That's the sort of circumstance that creates a fatality. Relatively safe as sold. A potential death-trap now (if I use the Al. knob).

I won't write more about electrical safety. I want to read about your minimalist superhet. I'm so interested in this that I intend to draw up the circuit Prof Coro promotes in his regenerodynes (and post it here). I have already drawn the block diagram, with tables showing frequency for crystals (etc). And I have 'my' version of his design on my work-bench. I used 6AK5 tubes for the mixer and detector (as he suggested) and I used a (fixed) IF frequency of 2025kHz. Not too far from his suggested frequency of 2000kHz!! And I use DC to supply the filaments. 175mA at 12V DC. Easy, easy, easy!! All good advice!! Thank you, amigo Coro!! I'm running David Newkirk's solid state LO circuit. I use a "high-C" circuit for the detector tank. I use powdered iron in the toroids!! Thank you David!! (Ha! I stole the whole design!! Not one original thought!!)

This set performs well. The regeneration control is as smooth as silk! The combination of +36 to +48V DC for the detector and LOTS of "C" in the tank circuit give excellent performance.

Perhaps I shouldn't have mixed two topics in the same posting - safety and receiver design - but I've written my words, and I won't change them now.

All the best.

Les Smith

Hi,

It is not correct that the problem goes away with polarised plug, at least not on DC. If you are unfortunately on the negative live "phase" of the DC the chassis has to be at negative line voltage. i.e. -230v in UK.

You would not believe the number of 230 AC plugs that were incorrectly wired in UK. Strangely some plugs would get "rewired" back the wrong way between service calls!

If the chassis is properly (not always the case) earthed then accidental contact with any metal part should be safe. i.e. grub screw on tuner or volume knob if it breaks. If AC/DC then there could be a problem unless shafts are plastic.

There certainly have been deaths in UK due to AC/DC sets. The reason US selected 110 volts is that there is a good chance of surviving. Not so with 230 volts.

Cheers,

William

My bench circuit is on a 15A breaker, and all of my "creations" are fused at rarely more than 1/2A. I use IEC connectors on my sets with the ground pin connected to the chassis. On most of my xfmr-less sets I include a safety relay that won't apply power if the chassis is not grounded or the AC receptacle is wired backwards. I personally wired all the recptacles in my house so I know they're wired right, but, I can't speak for anyone who might borrow one of my radios. One of he only "hot chassis" sets I have is a little all metal 3 tube Arvin that I've had since I was about 12 years old, and it has never zapped me. I also have a couple of S-38's that have behaved just as well.

I think anyone working around electricity must know that it can be dangerous. It's important to know the difference between the "hot" and the neutral leads, and the function of the ground circuit. A good understanding of Ohm's Law doesn't hurt either.

Hello Arnie,

I read your posting about how to suppress HASH with interest.
It may be my plan to do this will fail.
In short, I want to make a separate unit containing power supply, audio amplifier and speaker.

I have an aluminium box. My plan: to fit 'feed-thru' caps and suppression chokes to the cables in and out.
Now I read that I must use a steel box - not aluminium. Ouch!!

I thought (according to Gauss' law) that I would get a relatively quiet power source.
I'll let you know how my experiment goes when I have it working.

Les

27490. About the 6AK5/5654/6ZHE1P vacuum tubes for regenerative detectors

Yahoo group: regenrx (2016 — 2017)
Date: 2016-11-14 00:50:16 UTC
From: Prof. Arnaldo Coro Antich
Topic: 27490 Message: 27490

Dear amigos... have tested many 7 pins and 9 pins miniature vacuum tubes in my ¨classic¨ Hartley regenerative detector using screen grid voltage control...But because the 6AK5's and the Russian clones are so plentiful here, I have stayed using them .

High C tuned circuit for the detector is also a good idea... Operating between 2000 and 2500 kiloHertz for the regenerodyne , I find that during the daytime no signals leak into the detector, and at night , even with poor shielding of the detector , the presence of unwanted feedtrough signals is negligible....!!!! You can also make it tune from 2000 to 3000 to cover an exact one megaHertz segment (a la Collins 51J3 and 51J4 receivers)

You do need more current available for the detector filament and the first audio stage of the 2 stage amplifier that I prefer over the original ECL82/6BM8 of my early regenerodyne.

The latest version soon to be assembled uses a 6AK5 RF amplifier in grounded grid configuration, a 6AK5 mixer , driven from another 6AK5 as crystal controlled oscillator... The mixer output feeds the 6AK5 regenerative detector... The audio module uses a 6AU6 with DC on the filaments, and a 6AQ5 or EL84 according to what tube type is available.

This new regenerodyne will be built in a steel chassis and the power supply is on a separate chassis... well regulated B plus for the regenerative detector from a classic 105 volts gas discharge regulator... OR, as I have tried done many times, connecting three or four Russian 12 volts or 15 volts zener diodes in series to obtain 36/48 volts or 45/60 volts regulated.

The filament voltage when well filtered and regulated does help to reduce HUM ...

The audio output transformers that I have used have the proper impedance for the power output tubes used and have secondaries for 4 and 8 ohms.

My regenerodyne works fine from the LOWFER beacons band, the AM broadcast band all the way up to the 50 mHz or 6 meters band... For the higher bands I have tested using computer clock modules... for example a 48 mHz CPU clock module makes possible to do the conversion from 50 mHz down to 2 mHz, and the tuning range of the detector allows reception from 50.000 to 50.500... It makes a nice receiver to be kept on 50.110 or 50.125 to monitor band openings during the two equinoctial Trans Equatorial Propagation seasons...

I don't have a concrete plan for filtering the B+ but I do have an idea. The usual approach to filtering harmonics is a five pole pi filter as seen on many solid state transmitters. If I make one with a cut off frequency at about 20 KHz, the loss should be pretty high when you get to RF.

Hello Ed,

(I'm off the main topic now - Regen superhet - so please excuse me.)

I have a 12V to B+ converter here - it's noisy. It makes a LOT of hash!
I want to use it with my regen detector.
At the moment I'm running +36V DC on the B+ line - according to Prof Coro's experience.
I'll have to find a way to filter the noise - and I'll be interested to hear (or read) your experience in filtering. I paid $10 for it. It will supply any voltage from +45V to +180V, at 5 watts, by changing the "program" resistor.

From: J Ed
Topic: 27493 Message: 27493

I feel like this deserves its own thread.

I have some switch mode converters from Ebay. One is a buck converter and the other is a boost converter, both capable of a decent amount of power. I intend to run them both from a 12v battery...the buck converter will output 6.3v and the boost will have an adjustable output from 140-390v. This will lead me run a wide array of tube circuits.

The problem will be filtering out harmonics. I intend to place a five section pi filter in the power supply chassis. This should reduce harmonics in the RF band by at least 40 dB. A simple tube receiver can use this supply easily, as long as I could tackle the harmonic interference.

Filtering in a separate chassis or in the power cabling would help, too. Switching noise can be hard to tame but it's not impossible.

I placed the modules in a 9x5 Hammond chassis tonight. After spending a bit figuring out how to make standoffs, I used some PVC grommets that fit 4-40 screws perfectly. I may place some tape on the chassis under the modules to prevent arcing.

Hello Don,

I looked on QRZ-dot-com and saw your address.
If you tell me it's correct, I'll send some 5.000MHz crystals. HC49U or HC49U (short).
Also, I have some 11MHz rocks if that will help.

Let me know. Post from AU to Canada should be about 10 days.
I'm confident your set WILL work. You have the right balance of curiosity, stick-at-it and experience in how to think (from - I presume - your time with engines).

Ed, I think you'll find that you can easily get that much attenuation with a simple 2 or 3 order LPF with an inductor as small as 1mH. At least that's been my experience, but a few minutes with Elsie could save you some build time and parts. It's a good idea to bypass the supply input as well to minimize any conducted emissions on those lines.

This may be apocryphal, but as a youngster (age nine or so when I was beginning to do this stuff) I learned of a suicide that was successfully achieved when the person abraded the inner sides of his wrists, put salt on the slight wounds, then achieved his goal with leads from a husky 22.5 Volt dry cell.

It scared the dickens out of me at the time and has obviously remained in my memory.

Charles

Yes. The only difference between ac/dc and a transformer is the magnitude of short-circuit current. If you short the ac line the house system can supply several hundred to several thousand amps and you get a big spark. Short a transformer and the current is limited by the size and impedance of the transformer to a few amps, and not much spark. This is a distinction without a difference as it only takes a milliamperes to kill you. One can argue that ac/dc is safer because the voltages are lower. The only real hazard is the hot chassis problem, and with polarized plugs it goes away.

I'm with you, Don. I grew up with AC/DC stuff and I learned early on where the high voltages were. If anyone is prone to blindly grabbing wires and is worried about electrocution, perhaps they should take up a different hobby. Even a transformer powered set has "hot" power leads running through it to the switch and primary winding. I've been zapped more often on these sets that on AC/DC sets.

Name one person who was electrocuted from a AC Dc set. on 110 120 mains. I have known none ever and I have known a lot of people. Well over 1000. Millions and millions were built and used. Everyday we use stuff plugged in to main directly , some plastic which gives added

protection and some metal , especially in the past. 50sand 60s. I asked my Dad once when I was preteens . He said if you were in the bathtub and someone threw the radio in it would be dangerous. (same would apply to an electric drill BTW or a lamp) James Millllen worte a whole one page article on the subject in QST in the 1930s I have ithere and read it through last year. HOWEVER if you wish not to do that I have no problem with that either and I'll not be eating any casaroles either. ;>) I myself do not like hi power rigs like linear amps a such because I don't like being around that much voltage. The fact that there is a transformer involved gives me no comfort whatever. in fact i fail to see how that gives protection. Now if you are on a 220volt mais system then I would be nervous too and while I could steal that here from the clothes dryer or welder plug direct I won't. BUT on my rigs so powered you cannot touch them when running and they are built on wood not metal and that includes my PSUs My twin 811A linear and all these longfellow txs . And my PSUs are fused near minimums. Best protection transformer or transformerless is don't touch it and leave nothing exposed. Shunt feed also goes a long way and is used here .

Let me clarify, because "RF band" is a very broad statement.

Say we have a switcher that uses a frequency of 30 KHz. The lowest amateur band, 3500 KHz, is more than 100 times the frequency (I believe this is two decades). Designing a 40 dB/decade filter shouldn't be hard.

The thing to remember is that the harmonic signals won't ever be gone. The best I can do for receiver work is to reduce them lower than the strength of the signals I hope to receiver. For a broadcast receiver, this wouldn't be as hard as for an amateur receiver.

Per your suggestion, I'll play around with Elsie and see where it takes me.

Hi Ed,

The lowest frequency amateur band is at 472 kc, This apparently will be allocated eventually in the USA, too. Presently in the USA the lowest frequency amateur band is 160 meters at 1. 8 mc. Although not allocated in the amateur bands there are stations at much lower frequencies and we wouldn't want our power supplies to interfere with our operations there.

I have been able to see improvements in the background noise levels in my receivers when I turn off *all* of the switch mode power supplies in my shack - including the computers I use for digital modes and for DSP processing on otherwise 'legacy' equipment. There have been *no* exceptions. I use brute force 'linear' power supplies or even better - batteries when I can. Try operating on battery power when the power grid goes down in your area. The results are 'illuminating'.

Actually there are several US stations already on "Permission" license on 472 (630M). For us it is already permissable. We were told to give way to commercial traffic. There was just a two day event on 630m (472) this past weekend. However a PSU is not a transmitter and it should not be that hard to ensure it doesn't leak RF. So I think.

Hi Don,

They put plenty of hash into receivers sitting a few inches to a few feet away. That is the digital, switch-mode power supplies. The hash is radiated and/or conducted into the receivers. That was the whole point of the original post as I understood it. When I want to hear truly weak signals the computers and other digital futz MUST be unpowered (unplugged). For more casual use they can be used as part of the system. I haven't used *every* device on the planet but have not found any switch mode supplies or computers that are *dead* quiet. I have made some of them less offensive but not completely clean.

I'm standing my ground on this.

Hi Don,

I started by looking at the filters that are supposed to be on the AC line into the computer powers supplies. I installed missing filters, missing filter sections or reinforced the filtering. I added similar filtering on the output (DC) side but things like the inductors can get *large* for high current power supplies. The metal shielding helps too and I have done some of that. We have to make sure the metal pieces are well connected and then grounded. Aluminum foil as sold for use in the kitchen is awfully fragile and I had better luck using the heavier foil that is sold full of frozen lasagna and other such goodies. It is more durable and workable which helps maintain the electrical bonding once you have put it together.

Cables sometimes benefit from ferrite materials (sometimes not). Do what you can about those. Much of the time it has been difficult trying to determine the source of the hash so what works on one power supply might have no effect at all on another.

Meanwhile, I still get the best results using batteries and unplugging the digital/switching supplies. With stronger signals (and there are plenty) the 'hash' might not be troublesome or not noticeable in some parts of the radio spectrum. I have found batteries practical on tube heater circuits and for plate B+ supplies in receivers and low power transmitters (up to about 6 tubes) and a watt or two of RF power. That is NOT inverters, multivibrators, etc to change a 9 or 12 volt battery to 180 volts DC. It is DC straight from the batteries in series stacks.

There are other things I have seen on the internet but not tried. As usual - your mileage may vary.

Heh,

Some of the stuff I try doesn't work very well either (or maybe not at all). Most of the materials can be recycled into other projects (unless smoke is involved). Good luck with your regen/superhet.

I'm looking at the parts for one that uses battery tubes like the 1S4. I have several designs here that use two or three tubes with different 'architecture'. I'll see if I can transplant the most favorable bits from each and put them together in one radio.

I went a different way. The converter is running from a 12V battery, frequencies between 100-300 Hz are no problem. The voltage has to be filtered properly. To do this, the inductivity is very helpful, because with 200Hz the ears are already getting sensitive.

I know about somebody, who used an integrated circuit for car radios. Input signal was a sine wave, the ampifier output was feeded into a transormer 12V/230V. This way the signal is completely free from any noise.

** What is the 24 V line connected to the output rectifier?
** Seems like it is standing the output voltage on top of the battery?

The wires a and b are showing a square wave signal with a maximum of double voltage of the battery. Without D1 and D2 and without snubber, there is an overshooting up to 80-100 Volts. So the two diodes are rectifying the square wave voltage, but are also removing the overshooting. At this point i thought, why not improving the efficiency and adding the output voltage on top of the 24V.

- The 250-270 Volts are used for a small transmitter pa 2-4Watts and the stabilized 155Volts for receive and the transmitter oscillator.

- D9 is protecting the transistor, if the 155 Volts are decreasing slower, than the base voltage.

- My output power measures ~15 Watts. The power could easily be increased just by changing to a larger transformer. Above 15 Watts the MOS-FETs should be mounted on a heat sink. Don't forget the isolation.

- Increasing the frequency to 200-300 Hz doesn't make any trouble nor anything is getting too hot. A smaller core is neccessary, to transform the same amount of power and former 6V or 9V secundary windings can be used with 12Volts. In my case the biggest losses are caused by the copper resistance of the 2 x 9V coils. So it makes sense, to look for a transformer with a low coil resistance.

- It makes a little bit effort, to choose the right transformer. The primary / secundary turns ratio can be measured, when the transformer is running without load. The voltage is typically about 10% higher compared to the value told in the data sheet. If now the transformer is turned upside down (secundary <> primary), the opposite is the case. And don't forget the additional 24 Volts. If this is done wrong, then one might end up with a completely wrong voltage.

27517. BJT detector blocks for using in any regenerative receiver.

In the Desert Rat II receiver the diode detector D4, D5 is preceded by an emitter follower Q3 which acts as a buffer stage between the tank circuit and diode detector. I see that base bias resistor R6 has a rather low value of 10k, which unnecessarily loads the tank circuit. And there isn't any base stopper resistor which prevents parasitic oscillations of the emitter follower stage. Advantage of using a diode detector that it makes regeneration control more smoothly. When the signal from the tank circuit increases, D4 and D5 conduct more, decreasing its input impedance of the full-wave detector. The input impedance of Q3 is Hfe * Rl, Rl is decreased that means that the input impedance of Q3 is also reduced. The Q-Multiplier is more damped, making the oscillations weaker and hence the regeneration control more smoothly. See "Regenerative Receiver Design Blocks" at http://hubpages.com/technology/Regenerative-Receiver-Design-Blocks.

http://kearman.com/images/desert-ratt2-rf.png

In the uppermost circuit diagram below I have substituted the full-wave diode rectifier circuit by an emitter follower detector T2 which is biased near cut off. T1 is a bootstrapped buffer stage between tank circuit and detector stage. T1 and T2 form a Darlington pair in which T1 is sufficiently biased by R8.

In the lowermost circuit diagram I still use a full-wave diode detector. But I use silicon diodes 1N4148 here which must be biased by R13 of 100k, otherwise the detector won't function properly.

In both diagrams the base stopper resistor R4, R15 of 220 Ohms are mandatory, otherwise the buffer stages T1, T4 will parasitically oscillate due to the invisible parasitic Colpitts voltage divider.

- My output power measures ~15 Watts. The power could easily be increased just by changing to a larger transformer. Above 15 Watts the MOS-FETs should be mounted on a heat sink. Don't forget the iso lation.

- Increasing the frequency to 200-300 Hz doesn't make any trouble nor anything is getting too hot. A smaller core is neccessary, to transform the same amount of power and former 6V or 9V secundary windings can be used with 12Volts. In my case the biggest losses are caused by the copper resistance of the 2 x 9V coils. So it makes sense, to look for a transformer with a low coil resistance.

- It makes a little bit effort, to choose the right transformer. The primary / secundary turns ratio can be measured, when the transformer is running without load. The voltage is typically about 10% higher compared to the value told in the data sheet. If now the transformer is turned upside down (secundary <> primary), the opposite is the case. And don't forget the additional 24 Volts. If this is done wrong, then one might end up with a completely wrong voltage.

"I know about somebody, who used an integrated circuit for car radios. Input signal was a sine wave, the ampifier output was feeded into a transormer 12V/230V. This way the signal is completely free from any noise."

But when the power amplifier is switched off, will the primary of the transformer generate a high voltage spike, caused by the self-inductance of the transformer, which will destroy the PA stage? And there should be a feedback circuit to stabilize the voltage at the secondary of the mains transformer.

Hi everyone,

This is a very interesting thread and after reading the earlier posts on the subject I thought I would share my experiences with switching power supplies. This post may be of most interest to those who want to home-brew a switching PSU.

From early "bad" experiences with switching/switch-mode psu's it seemed like an interesticg challange to try and make a silent switching supply for a regen tranceiver project I was working on at the time (Parset) which is shown here...

http://www.qsl.net/m0ayf/Paraset/M0AYF-Paraset.jpg
http://www.qsl.net/m0ayf/Paraset/M0AYF-Paraset.jpg

The power supply needed to operate from 12 Volts DC and provide around 200 Volts (noise free) and to cut a long story short the project was successful and "silent" though I admit it was noisy on the first testing.

I found the secret to that truly "silent" background was to sacrifice a little efficiency by way of s-l-o-w-i-n-g down the switching waveform slightly. That is to slow the rise/fall time of the switching waveform which is echnicaly very easy to achieve with simple R/C circuits.

I should also confess to operating the switcher at fairly low frequency of around 80 Hz (not critical) as this permits the use of regular mains power transformers found in the junk-box.

The other secret to the silent background was to adopt the sound advice allready offered by Arnie Coro (CO2KK) and to mount the PSU in a steel box to provide both magnetic and electrostatic shielding. Plastic or alloy boxes are no good.

As for the technical detail I would direct you to the following web page and the experiences of Ronald Deckkerand in his quest to build a "silent" 90 Volte plate supply for use with battery valve radios.

Really silent DC to DC conversion.

Very interesting thread indeed... that made be go into present day really professional totally isolated from the AC power lines systems...

The way things move is clear... You do not generate a square wave, or even a staircase type of waveform...

Professional UPS systems that cost a lot of $$$ generate a very nice looking extremely low distortion SINE WAVE... that is operated at 50 or 60 Hertz depending on the country where you live.

In Cuba we use 60 Hertz AC MAINS:.. so a system intended to provide full time power UPS to for example a DATA CENTER or the MAIN CONTROL of a TV station is designed around a huge battery that is kept fully topped automatically.....many, many amperes...

The battery provides power to the system that consists of the sine wave generator that feeds a huge power amplifier ... The battery has enough storage capacity for maybe 10 or 15 minutes, giving a logical margin for your beautiful No.1 Diesel powered back up generator to start... and it No.1 fails gives time for No.2 Diesel to come into service...

During the time lapse when the Diesel is not charging the huge battery bank... the equipment is kept powered from the same source... so there is NO SWITCHING TRANSIENT:... Your equipment is always receiving its AC power from the huge 60 Hertz ¨ audio amplifier¨.... Usually the system uses not one but two or four power units , two synchronized normally and two ready to step in as required if there is a failure.

No switching transients !!! and if the Diesel's do not start (they provide AC also to the vital airconditioning equipment) then all sorts of alarms start flashing , ringing and shaking so that a hopefully automatic shut down sequence is started.

Now back to the regenerative power unit... you connect your 12 volts battery to a 60 Hz (or 50 Hz) sinusoidal oscillator that feeds a standard transistors power amplifier... that is connected to a standard transformer that feeds the rectifier module... In other words, you go from DC to DC without the dreadful presence of the the square waves of a switched mode power unit...

73 and DX

27522. Regenerative receiver with a product detector.

Yahoo group: regenrx (2016 — 2017)

From: dawmast@...
Topic: 27522 Message: 27522

A regenerative receiver with a product detector, like this one at
http://hubpages.com/technology/High-Performance-Regen-Receiver
http://hubpages.com/technology/High-Performance-Regen-Receiver "A High-Performance Regenerative Receiver - HiRegen".

Here is a schematic of an autodyne (self oscillating) product detector from Elektuur November 1987.

T1 is the RF preamp. stage while T2 is a synchronised regenerative product detector. Armstrong type RF feedback is via C5, L2b and P2. When T2 is oscillating, the amplified RF signal is taken from the drain of T2 and fed to G2 of T2. This signal is multiplied by the sidebands of the AM RF signal at G1 and the difference product, which is the demodulated AF signal is taken from the source of T2 and fed to an LPF with C13-C15 and L3.

https://www.uploadarchief.net/files/download/dcr_mos.gif
https://www.uploadarchief.net/files/download/dcr_mos.gif

Advantage of using a product detector in a regenerative receiver is the good selectivity, because the difference products of adjacent channels lies out of the audible range in the baseband. An LPF with a corner frequency of 5 kHz at the output of a product detector improves the selectivity. In fact an 'IF filter' at AF. The adjacent channel selectivity of a product detector is not dependent of the resonance curve of the main tank circuit which precedes the detector, unless the product detector does not do envelope detection secretly. If that happens, a strong signal farther away will break through by unwanted envelope detection.

I think that using product detectors in regenerative receivers should be further investigated. In regenerative receivers envelope detectors are usually used.

Topic: 27522 Message: 27523

The T2 g2 connected right to the drain, how does that work? g1 gets positive feedback via the coil, but g2 gets negative feedback from the drain. Also i think the g2 DC voltage must be rather higher than

in usual usage? In the text below, is “multiplied” the verb you actually meant to use?

thanks- Hue

T1 is the RF preamp. stage while T2 is a synchronised regenerative product detector. Armstrong type RF feedback is via C5, L2b and P2. For those who concerns I had to order some tubes for my TCS station so I bought two 3L6s as well. Now the project has a 50L6 and two 35L6s which does nicely. It is not an easy project though and is fighting me at every turn.
Crystal osc works, AF pa works and PSU works but the busines section does not yet like the mix. Eventually it will happen.

Did you build that or did someone else?
****

Yes, I built it a few years ago after catching the "paraset bug" and to satisfy curiosity about using a regen as a CW receiver.

It works well except that the paraset does not have provision for a variable coupling of the antenna, its pre-set so sometimes it can be overloaded by realy strong signals though in practice this happens very rarely. Its remarkabley sensitive for a receiver with just a couple of valves/tubes.

Thanks again for the kind words,

73,s

Des (M0AYF)

Questions, gentlemen:
the first paragraph below, what effect do you notice, with the grid tapped down on the coil?
the second statement, about the detector being pulled by SSB freqs close to the HF osc, how is this experienced? Does it cause signal 'warble' ?
thanks-
Hue

>By the way, my favorite regenerative detector circuit is the HARTLEY, using a pentode tube, with screen grid voltage control of the regeneration... Polishing the circuit I found out that the grid connection to the tank coil placed about 15 to 20 percent down the coil instead than at the top, was a good idea too...
73 and DX, Arnie Coro CO2KK

>When receiving SSB, the detector has to oscillate at one particular frequency ~1.5kHz away from the center of that receiving signal, to act as a BFO. Low frequencies of a voice are only 200-300Hz away from the detector frequency and sometimes they are strong, so the detector is tending, to lock into them. Now the detector is overloaded.
Best regards,
Bernd

** what effect do you notice, with the grid tapped down on the coil?

Reduced influence of the regeneration control on the frequency.
Slightly increased Q of the tank circuit.

** about the detector being pulled by SSB freqs close to the HF osc,
** how is this experienced? Does it cause signal 'warble' ?

Strong signals are causing distortion, here is an example:
https://youtu.be/fV1QeA3NJ6U?t=360 https://youtu.be/fV1QeA3NJ6U?t=360

Dear amigos:

Second to none , IMHO the near optimum tank circuit is made using a high quality glazed ceramic coil form.... wound with silver wire (a luxury indeed) and a ceramic insulated air spaced variable capacitor... Optimize the circuit by connecting the grid to about 20 percent down the top of the coil, more or less, and the Hartley cathode tap also about 20 percent UP from the ground connection.

Of course that a standard circuit configuration using other materials for the coil form and with the grid connected to the top of the coil, and the cathode tape to about 25 / 30 percent from the bottom of the coil will work nicely , BUT, the glazed ceramic coil with large diameter wire spaced one wire diameter appart in a grooved coil form... is again IMHO the optimum....and this approach is also valid for building VFO tank circuits...

I am now stuck with my decades old TS820S Kenwood transceiver...it is now receiving OK, but no screen voltage on the 6146's tubes, so ZERO output... Seems like a 6146B screen electrode short circuited and that has damaged the voltage divider that feeds the screens from a 260 volts DC power supply...

After spending four days with that very sophisticated radio transceiver that uses a myriad of MOLEX type multiple pins with wire wrapping interconnecting the modules... I have decided to this will be the last repair job on that radio, and what little time is available will be spent, from now on designing and building my new ham radio station... using a regenerodyne and a separate transmitter.... of my own design... so will keep you all up to date on how the 2017 station project goes along, with the hope it will help others to enjoy home building of simple rigs !!!

27531. 6EH7 Detector...Then What

Yahoo group: regenrx (2016 — 2017)
Date: 2016-11-30 06:16:12 UTC
From: J Ed
Topic: 27531 Message: 27531

So I have some 6EH7 tubes I've hoped to one day use for RF stuff. They used to be RF and IF amplifiers used in televisions and they have a lot of transconductance. One would hope that a complicated receiver using two or three of these would have a huge dynamic range.

Still, I'm contemplating one in the front end of a regenerative receiver. For frequencies below 20 MHz, I doubt I'll need any gain in front of the detector. So I can use the tube to detect shortwave signals.

If I were to commit to such a project, what would I want to do next? Assume a common Armstrong-type detector with a tuned grid circuit and a tickler coil. Would it be simple as...say...40 dB of audio gain across two amplifier tubes? With another tube or two, I'd be able to create an active audio filter and reduce the adjacent signal interference. Not sure what else I could do to improve the circuit beyond a simple 0V2 type of receiver.

Ed AE7TE

With this tube's high transconductance, maybe, i thought, it would function decently on ½ the rated filament voltage – or less, much in the
way the ARRL 6F8 project or the 1940s "B+ less " circuits. I'll maybe add that inquiry to the projects list – get a 6EH7 and try it on my tube
tester with lowered fil voltage.

After reading a QST article in the 1960s, i made a tube adapter for the 6EH7 to plug into the 6BA6 RF socket on my Lafayette KT-200 (HE-10)
receiver. It made a BIG difference.

Attachments: 1 described; binary payloads are missing from this source WARC

Recently I have been playing with my breadboard station. Experimenting with a 6550 tube in place of the 616 I had been using. Results were encouraging so I continued and decided to build a new higher voltage PSU for the transmitter from my junk box. I had an odd Hammond transformer with a 250-0-250 winding and I had a Hammond 6 or 12 229 series transformer so I married both to get the required voltages. I used what I call to myself a 3/4 wave rectifier system with two diodes and filtered it with a pair of 100uf 500 volts caps in series. Since building one a few year ago for my twin 811A linear it has become my PSU design of choice and everything now running here save one is of that design. It is very quiet. I built the load resistor from a string of three 10 watt 27K wirewounds and realized I could steal power from the last resistor joint to ground and use it for my RX with a little wiggling. I dropped it further and wound up with 80volts feeding the regen (design is from the 1943 ARRL handbook except I used a 6SL7.) I have been running it on batteries (ten 9 volts). Right away it worked and hum was not objectionable EXCEPT on the cusp of regeneration. Just to see I added a 100 uf across the incoming B+ power right on the regens terminal strip. Worked like a charm. Even though hum was well below annoying before when on the edge of regen the regen was able to pick it up. The extra right at the set killed it. And I am going to leave it so. If there is one thing I have learned with regens . When you get it right STOP!
I have sent a very enjoyable evening with my station SWLing and doing some ops also.

The big tube is a KT88 North American version . A 6550. They wire exactly as a 6L6 (7AC pinout) and can stand above 600 volts. I have heard as high as 900 but I think for me 650v would be where I would draw the line. I had wanted to try a KT88 for years and discovered there was an AM HF set used by the Canadian navy that was a pair of KT88 modulated by a pair of KT66s. Even as a direct sun it does show power improvement and significant on this old breadboard set. The new PSU runs it just below 500 volts key down in tune which is light but it was the only transformer in my junk box. I may buy a new Hammond for it and raise the bar again. However I don't want lose the abilty to run the regen from it so will be willing to spend the extra if need be for a multi voltage winding. The PSU is enclosed because it is ugly however here is how it is made.
I ignored the transformer centre tap and used the outer ends netting me 500 volts AC fused on the 120 primary with a 3 amp fuse. The high side (upper in a schematic) goes through a 10 ohm 10 watt wirewound and connects to a 1n4007 diode's positve termnal. The low side (in the schematic in my minds eye) goes straight in but has a 1n4007 connected to it also at its pos terminal. It goes up to the other diode but connect to the upper line AFTER the diode (two N terminals are connected together.) a pair of 100 uf 500 volt electrolytics in series at connected across the output Positive to upper wire (just past where the diodes meet) and neg to the bottom or neg line. I suppose i should out equalizing resistors across them but often dont if there is only two and they almost meet the rating anyway. (If there were three or more i would always do that.)
This feed a series of three series connected 27K wirewound 10 watt resistors used as bleeders mainly but also dropping resistors for the rx voltage. If I had had three 10K 10watt wirewounds I would have used them for the last 27K resistor as it would have allowed me abit more leeway in regen voltage selection. However I did not so I was able to reduce it further right at the set. As stated I added the extra 100 uf cap at the regen so any hum pick up or other undesireable crap would be dealt a final blow before entering my set. I have done this before so got to liking it. this is probably not the most exotic PSU design . In fact some may find it laughable BUT as someone who has fought hum on AC supplies especially with regens as well a small transmitters I have come to like this design simply because for me it always works. The diodes do not need bypassing either. in fact it is quieter without it. How do I know that? Because I took the time to try it both with and without .01uf caps as diode bypasses. Hope that is enuf info to satisfy your curiosity. I have now four PSUs running here carrying this design. I prefer it myself to a bridge as it is for me quieter. I am totally results oriented so that is what I have and how I arrived here.
donVe3LYX

Oh Yeah I forgot. Currently I was able to buy the 6550 tube for LESS then a 6L6. ($37.95 USfunds) It was not always so which held me back from trying this for several years.

27543. Torn.E.b. in pot-metal production ?

Yahoo group: regenrx (2016 — 2017)

From: Hubert Miller
Topic: 27543 Message: 27543

Someone has asked me if a German, Torn.E.b. regen receiver weighing 34 lbs. is likely to be composed of pot-metal (wartime expedient)
compared to the earlier non pot-metal production. The receiver is dated 1943 and that was the year (as far as i know) that pot-metal
production started. Before that year, definitely safe, and in 1944 and 1945, pot metal definitely - i mean in ground radios. This example
is 1943, and i don't have it to examine, hence the question.
thanks-
Hue

There is still a lot of difference between zinc and potmetal which is essentially made from anything that with melt and pour together Or in my industry garbage metal we called it. Zinc was commonly used for Carbs. Potmetal for trim castings that were to be plated anyway. Potmetal in a German radio? Ich glaube nicht. Es ist nicht die deutsche weg!

So far i have figures for the receiver weight of 22, 34, 41, and 44 lbs.
The 22 lbs. sounds realistic for the design spec weight. When you add that to the separate battery box with its vibrator supply and wetcell 2 volt
battery, which likely adds maybe another 15 lbs., you have one pretty good pack load for the carrier.
At 44 lbs plus the battery box you have a load that becomes unpleasant.
I have 2 of the receivers that suffer the "zink-pest" metal decay.
One has a coil turret with some of the sections expanded, so that the turret clearance is no longer there and the turret is jammed, cannot rotate.
The other radio has a more basic challenge. The front panel has expanded and now is jammed tight. I have tried every trick and found no way
to successfully remove the radio from its cabinet. A slight additional complication is that the metal of the front panel is also now kind of fragile.
You might think your usual front panel might bend if screwdriver crowbarred. Not this metal; it will instead crack, like it was dried clay.

I had a GN-45 hand cranked generator for the BC-654 radio. I was amazed when one of the protuberances, the hood for the power connector,
cracked into pieces just like the German pot metal.
-Hue

Aluminum casting is a lot of fun. Does not require anything exotic. Patterns can be made from Styrofoam and buried in the sand or pressing can be made in the sand and poured as an open mold as long as they are level. A texas weedburner of about 55000btu (Princess Auto or Harbour Freight) will do the melt and crucibles can be made from Exhaust pipe by anyone with mild welding skills. Wooden pattern work best for pressing sand for open pours. Scrap aluminum can be cut on a standard table saw into small enough pieces to melt. Not for everyone but an awful lot of fun and very interesting.
Zinc can be cast at lower temps and sometimes in hard rubber type molds. If the XYL molds chocolate she can teach you everything you need to know. If that is not an option. Most towns of any size will have a aluminum foundry of some type. (if you think not ask around. You will be surprised.) If you cosmetically repair your old piece with body filler etc and take it to them they will cast you a new piece using you cobbled together cosmetically repaired piece as a core and it will be affordable. Not to mention very interesting.

I am building a low voltage receiver from a schematic by VK6FH. In this he shows pin 4 connected to 12 volts, pins 5 and 8 connected to ground. There are no connections shown to pin 9 -- does this make sense? Does the tube actually contain two filaments as shown in the schematic?

I saw a receiver demonstrated by VK3YE -- set up for the broadcast band and also 160m operation. I am pretty confident building this thing, except for wiring to the filament(s) and also it will be interesting to see if my loop stick works -- it has a second set of low inductance windings wired in series with the larger one -- I have not given thought to which way the sense should be on the smaller coil to obtain regeneration.

Info appreciated - I realize its a very simple circuit.

I did check the variable cap I have - it has 40 - 419 pF so it should give me BCB with a loopstick harvested from BCB receiver.

Curt

There's an error. A 12AU7, as well as other twin triodes in the same vein, have two 6v filaments. One runs from pin 4 to 9, and the other runs from 5 to 9. For 12v operation, put 12v across 4 and 5. For parallel operation, place 6v on 4 and 5 and the return for 6v on 9.

I built a regeneration with a 12AU7 and 12AU7 like this. I used a 24v power brick and placed all filaments in series, using a 10 ohm resistor to limit current.

You mentioned ignoring the center tap on the power supply transformer. I assume you are running a bridge rectifier, if so then the center tap will provide half the voltage of the bridge output. Just add a filter cap and good to go for 250V for the regen.

Curt,

There are two filaments, one for each triode. One end of each filament is connected to pin 9 so feeding 12 volts across pins 4 and 5 gives 6 volts across each filament. It's a little odd that the schematic shows pin 9 twice but you could think of it as pin 9 internally connected to pin 9 :)

LIGHTWEIGTH SOLID STATE „BERTA"

Solid state substitutes of RV2P800 operate better than original vacuum tubes. The teceiver is powered by 4 Li-ion cells (from 14.8V laptop battery). NOTE: Transistors Q1 and Q2 in cascode circuit have different cutoff voltages. The circuit is more complicated with equal transistors because the gate of Q2 is powered by voltage divider.

No I believe if you reread you will see I said I do not use a bridge however 250v is too much for the regen. The design I used was intended for 45 volts but will work to 90volts. I used about 80v. I found on some advice Dave Stinson gave on building ARC5 power supplies (which may seem unrelated but is relavent) that stealing taps of the bleeder resistor string works very well and uses a lot less parts. On a regen or most receivers for instance current draw is very low compared to a transmitter. I have tried that too and had it on my no 19 set PSU for a couple of years (275v for low HT from centre tap and 550v from top end for PA tube) but recently (Nov) redid it this way and came away with a much quieter PSU. I have so redone most of my shop supplies to this design because there is no detectable hum on my signal and I can power my regens and receivers with no concerns.

Fixed regen detector, that would be along the lines of a Super Gainer. May want to move up to 2.0mc, if only because the MW BCB now extends to 1.7mc.

If your regen detector is fixed, that means you will be tuning with your mixer's local oscillator (LO) which is fine. Actually, it's pretty much the standard architecture for most superhets, regen or no.

I might suggest, however, since the LO is much higher in frequency and therefore subject to greater variances and such, to keep your tuner at the lowest frequency portion of your receiver, which is why I always recommend a xtal controlled LO and a regen tuner that covers something like 2.0- 3.0mc. Down there, regens behave and tune very nicely, well on par with any other receiver type. It makes things much, much simpler when it comes to band selection (just change extals) and calibration between the bands.... with proper band xtal selection, that is....

A low band tuner with a high band xtal converter, is really all a Regenerodyne is. Regenerodynes always tune at the detector stage, never at the LO stage. That's Frank Jones' turf.

I know this post is dated november, and me, your poor listowner has been long engaged elsewhere and umpteen different levels, but from time to time I still check in here. I read this and just wanted to respond. I think Prof. Arnie already covered pretty much what I've just posted. But as one of the Regenerodyne developers, I always take the opportunity to do a shameless plug for it, lol!

BTW, my NRR station for the past two, and upcoming third event this Feb, is entirely HB with a 6V6G MOPA and... you guessed it.... my old Regenerodyne that I built back some twenty-five-odd years ago. Still kicking on all bands 20, 30, and 40m. Great communications receiver. If you don't mind code communications with 1930-era filtering!

Happy New Year!

Hi Alex. I'm not an expert or a perfectionist. Most of my circuits are copied from others, or from just guessing. Lately I've been using an Excel spread sheet to do the circuit calculations with some success. Excel has all the math capabilities needed. I simply take all the equations I can find and program the computer to give me the apporximate values for each component, using data from the tube characteristic curves. Since there is so much variation between tubes of the same type, I don't try to get exact values. The good thing about the program is, I can change an input value and instantly see the result without going through the tedious calculations over and over. Not perfect, but good enough is good enough. "Hollow State Design" by Grayson Evans is a good place to start. He even suggests using a spreadsheet too.

Leonard

Hallo Leonard,
this is Alex I5SKK. I watched all your posted files in the subdirectory of the section and found them really interesting. It would be possible to change ideas and opinion directly via email, around the tests you made, as I saw a lot of tests and different versions of regen RX you made. I'd be really grateful for this. Many thanks in advance and once more, my best wishes to you and the group !

New kit out from 4SQRP folks. Modern take on WW2 Paraset. Receiver is a regenerative receiver -- classic "Armstrong" style. Instead of variable capacitors, they use varactors, both for tuning, and for throttle. Because it is designed for the 40 meter CW band, tuning range is slightly less than 200 Kc.

Crystal controlled.

Toroid for tuning coil. Grounded base un-tuned RF amplifier, pretty standard audio.

MOPA transmitter side, gives 5 watts.

Check it out..

I got one from the first run. Happy I did because the first run sold out in about 2 days. A really first class kit! I had built a prototype from PCB got from N5IB back in the summer and paired with a 2fer transmitter. Worked very well. Most stable regen have ever used. When the 4SQRP kit came out, bought one because the front panel, silkscreen, onboard key sold me.

After completing the kit in 4-6 hours right after Christmas, have been prowling 40M during the day with the radio. It is rock steady on frequency and regeneration. So far have worked 25 stations in 15 states, surely the real spies would have been happy to carry one of these modern implementations into the war zone.

My 2 cents...

Attachments: 1 described; binary payloads are missing from this source WARC

BAD REGEN STAGE: The regen stage of „Bayou Jumper“ differs from Armstrong circuit because in katode (source) is involved degeneration (negative feedback) at audio frequencies. It decreases modulation index and sensitivity. To avoid this drawback, you should use for demodulation a separate diode connected to COM rail.

Date: 2017-01-16 07:23:40 UTC
From: Rob
Topic: 27572 Message: 27572

what is sulfate of zinc and acidulated water and saturated copper
sulfate crystals ?
Do we have any chemists out there?

I found an old time article how to make a battery and it specified

sulfate of zinc and acidulated water and saturated copper sulfate crystals

http://www.learnmorsecode.com/regen2/battery02.jpg

The article said to use ZINC SULFATE
or
ACIDULATED water.

So I got look up ZINC SULFATE on the web and is says we can buy 220mg
zinc sulfate capsules...to eat.
huh?!!??
edible batteries?

Zinc Sulfate (220mg) - 100 Capsules
Zinc sulfate is an inorganic compound and dietary supplement. As a
supplement it is used to treat zinc deficiency

but hey...it did say "OR"
and when I look up acidulated water it said

wiki:
Acidulated water is water that an acid has been added to it, usually
lemon juice, lime juice or vinegar. Citric acid and ascorbic acid can
also be used.

Acidulated water can be made by combining 1.5 tablespoons vinegar or 3
tablespoons lemon juice.

sooooo..... OK... this doesn't sound real toxic or dangerous to show
and tell kids battery chemistry....

AND THEN
there is the saturated copper sulfate....
which is readily available at th eharware store
ROOT KILL copper sulfate pentahydrate 99%
and instructions on the web say:

First, you need a saturated copper sulfate solution so the crystals can
form as the liquid evaporates. All you need to do to make the solution
is to stir copper sulfate into very hot water until no more will

dissolve. There are two ways to grow the crystals.Apr 26, 2014
How To Grow Blue Copper Sulfate Crystals - Science Notes and Projects
https://sciencenotes.org/how-to-grow-blue-copper-sulfate-crystals/

OR
just buy 10 pounds of crystals from a seed supply house for $32.

So is this feasible or would parents be pissed if they knew their kids were near these chemicals?

I was thinking more along the lines of building the battery...stacking a
dozen oilve bottles in a wooden crate....
and running a tube regenerative receiver.
I am not doubting the amperage available from a pile of potatoes but
and this is the BUT
I've only seen LED circuits and calculators that run on button batteries
used as examples
of what these batteries can do.
So... have we any potato battery measurements to calculate how many of
these cells adds up enough amperage to
play in tube land?
And then there is the metal purchase to consider.
Copper and zinc are available but adds up real quick when you need
hundred batteries made of potatoes.

From: Leonard Meek
Topic: 27579 Message: 27579

Hi guys.

I just posted another evolution of my Mk.14. I put the 956 back in as an untuned RF amp between the tuned RF preamp and the detector. Iknow, I know, a regen detector is not supposed to need a preamp, but it helps when you have a crappy antenna. I'm still fiddling with that audio feedback loop and I don't iknow if I'll keep it. So far, it's working better on 30 & 40 meters and tunes sharply down to about 900 meters. SSB is good but shakey. I'll check tonight and see how well it does on 20 to 10 meters. I don't know who I copied this idea from but it may turn out to be my favorite circuit.

Is your purpose to make a retro battery that you intend to use regularly, or to demonstrate to kids how to make a battery? It's not clear which from your post.

If the latter, there are many simple recipes for batteries that are kid-safe. Just about any combination of two dissimilar metals and some sort of electrolyte will work. I have my freshmen build batteries from pennies, aluminum foil and paper towel disks wetted with electrolytes of their choosing. Coke/Pepsi, ketchup packets from fast food drive-throughs, fruit juices (including fruit), mouthwash, energy drinks, etc. have all sufficed to power up a basic calculator using 3-5 cells. They've even shown that disks sliced from bananas work great with a penny on one side, and aluminum foil on the other. The more ambitious students have opted for an aluminum foil ball surrounding a copper scrub pad, whose larger area allows for much higher currents. With 1-3 cells, these will run a motor (lye-based drain cleaner works great as the electrolyte, but is dangerous, so should only be offered to the older kids with adult supervision; use vinegar with the younger kids), or light up LEDs (these need more cells).

If the former, let us know.

The purpose is to make a retro battery that has enough power to run a tube regen receiver....
to show and tell how they did it 90 years ago.

NOT have kids handle any of the ingrediants.
I've built the pennies/foil cells with my kids 20 year ago.
We never got any USEFUL voltage or amperage. Just lit an LED.

I think I stumbled on this perfect answer:

What Happens in a Battery if Zinc Sulfate Is Mixed With Copper Sulfate?
by Serm Murmson

Chemical reactions can generate electrical energy from the exchange of electrons. A cell that uses the electrical current from a spontaneous chemical reaction is called a galvanic or voltaic cell. A battery is an example of such a cell. A battery is specifically constructed to ensure that its chemical reactions occur in a controlled and reliable manner.

The Nature of the Chemical Reaction
Batteries generate electrical current due to the exchange of electrons in a spontaneous reduction-oxidation, or redox, reaction. In a redox reaction, one element loses electrons: it is oxidized. Another element gains these electrons: it is reduced. The elements used in a battery are selected due to the difference in their oxidation and reduction potentials. For example, zinc loses electrons more readily than copper. A redox reaction will be spontaneous if the difference in the relevant cell potentials is positive: the system will move to release energy.
The Construction of a Battery

The cathode is the site at which reduction occurs in a battery. The anode is the site at which oxidation occurs. In many voltaic cells, the cathode and anode are made of the respective solid metals involved in the redox reaction. In order to provide ions necessary for the chemical reaction to take place, the anode and cathode are suspended in solutions containing the respective metal ions. These two solutions, called electrolytes, are connected via a membrane or barrier. In some cells this is called a salt bridge. The function of the salt bridge is to allow some ions to move while keeping others isolated in the respective electrolytic solutions. Once the anode and cathode are connected via a wire, the electrical potential difference will cause the reaction to occur. Electrons will flow over the wire.
The Zinc and Copper Battery

In a zinc-and-copper battery, the chemical reaction involves the transfer of electrons from solid zinc to copper ions. The zinc is therefore the anode; solid zinc is oxidized. The copper is the cathode; copper ions are reduced. The electrolytic solutions can be zinc sulfate and copper sulfate. When the zinc is oxidized, new zinc ions fall into the solution. When the copper is reduced, copper ions are displaced out of the solution onto the cathode. The negative sulfate ions in the copper sulfate solution can flow across the bridge to account for the creation of positive zinc ions.
The Importance of the Salt Bridge

If the salt bridge were not present, copper ions could come into contact with solid zinc. If this were to happen, both reduction and oxidation would take place at the solid zinc. Copper would build up at the anode, and the electrons would not be able to be harnessed for electrical work. Depending on the extent of the mixture of electrolytes, this could diminish the life of the battery, or even make it completely unusable for electrical work.

Amperage is a direct function of electrode area, so it's just a matter of parallel connection of as many cells as needed to get the job done. The copper scrubpad battery is capable of short-circuit currents of an ampere or so, and has an open-circuit voltage of 1-2V per cell (the exact value depends primarily on the metals you use for the electrodes). These are in line with what other retro formulas yield.

The material you posted is a generic description of all electrochemical cells: You just need two dissimilar metals, and an electrolyte between them to act as a salt bridge. There is nothing particularly magical about zinc sulfate and copper sulfate; it's just that it was used in an early cell (invented by a guy named Daniell in the early 1800s) that happened to emit less hydrogen gas than some earlier designs, and so it saw a lot of use in early telegraphy. Daniell cells typically yield about a volt or so each, so you'd need batteries of several dozen to supply the typical B+ of our retro receivers.

I like the boiled potato-based cell; it is remarkable that boiling has such a dramatically good effect on the resistance. I've never tried to stack enough of them to get to 22 or 45V, but if I can resist the temptation to make french fries, I'll have to give that a go the next time there's a rainy weekend here...

--Cheers,
Tom

I have not built a potato cell yet .... I learned about it a few days ago.
My interest in Daniell cells is longevity and overall safety.
Its described as having a long service life. I have no numbers.
I thought if I built a few dozen cells and wooden crates I would get the
desired voltage and amperage levels.

On 01/18/2017 03:09 AM, Tom Lee tomlee@... [regenrx] wrote:

I'm sure you can get the Daniell battery to work well. Be sure to post
pics once you get it all built. I'd love to see one powering up a regen!

--Cheers
Tom

From: dulmagedon@...
Topic: 27586 Message: 27586

Always curious of such things I grabbed a raw tater and stuck it with a u shaped copper wire. I took a removed blade of a small variable cap I had modified (aluminum) an stuck it in between. .624 volts. Then I took a nail (steel) and tried it instead of the aluminum . .454 volts. Now I wonder about washing soda (Arm and Hammer) I have used it for cleaning filthy automotive parts (sort of reverse electrolysis)but never check the voltage produced with dissimilar metals. I applaud all such experiments.

When I was a kid my favorite book by Alfred P. Morgan didn't involve radio, it was titled:

Adventures in Electrochemistry

As I recall, lots of home made battery (cell) ideas in that book - I was most interested in the Nickel plating experiment though.

Hopefully this book can still be borrowed from the library, his used books command astounding prices.

How about using NiFe cells? Iron outer case/electrode with nickle
plated electrode enclosed in it. Potassium Hydroxide electrolyte.

1.2volts though but rechargeable.

Cheers,

William

Hi Bill,

Isn't that electrolyte known as caustic or something like that. Probably not any more dangerous than the sulphuric acid in the lead-acid batteries we all know and love. But not something for kids to play with.

Regarding electrochemistry, everyone probably remembers the Burgess Battery company and it's well known red and black-white striped batteries that were made here in my town of Freeport IL. Fewer probably know that Dr. C.F. Burgess was a noted electrochemist who spent his life consulting and inventing in the field as well as running the company that bears his name. At one time the Department of Electrochemistry at the University of Wisconsin bore his name, and the original battery company he worked with, the French Battery Company, lives on as one of the major battery manufacturers: Ray-O-Vac - a term trademarked in 1921 for batteries used in vacuum tube radios.

blockquote, div.yahoo_quoted { margin-left: 0 !important; border-left:1px #715FFA solid !important; padding-left:1ex !important; background-color:white !important; } I finished putting together a one tube regen this evening. And unlike the other attempts in the past this one howled, squealed and warbled.
Once I thought I heard a couple of words but it may have been wishful thinking.
Anyhow, I would like to tame this beast down and actually hear coherent noises.
The circuit is the WW2 prison camp RX with the 6sk7, as seen on n6cc's blog page. Already got I think I may need to alter the number of turns on the coil.
The grid leak I used is 100pf/ 2.2 meg. It was already made and in the box.
So far I've burned out one pot, may need to add a resister in series.

Having just build a Bayou Jumper and gotten it working this past weeke, the regen is very smooth and has plenty of sensitivity for the 40m band locally. Mine covers from 7.003 to 7.143 MHz so a steady and slow hand is required for careful tuning as it uses a standard 270 degree potentiometer. One other builder has fitted a ten turn pot to his to slow the tuning rate.

There is a Bayou Jumper Yahoo group for further discussion about it. A second run of kits was just announced this week.

I noticed from the photo that the screw holes in the corner of the panel are not used. I guess that's dependent on the internals of the wooden carry box used.
Still, this is a finish item that looks hokey. I would try to fill those holes with screws, even if they don't do anything. To my eye, pan-head slotted screws look
better than the shiny Phillips used to hold the panel in the photo.
I think the hinges on the wooden box may become a problem also, if the lid is hanging open. I think eventually the weight of the unsupported front door
will eventually tear the hinges loose or crack the wood. If i had designed the set, i would have changed the format from 'landscape' (horizontal) to
'protrait' (vertical). That way the door could be opened and the set operated in that position with no weight stress on the hinges.
What do you think?

I think the person that took that photo hadn't at that point put the screws in the 4 corners. The screws are required otherwise the radio will fall out of the case if turned upside down.

Probably the person taking the picture didn't think anybody would nit-pick such a trivial detail in a photo and chose not to replace the photo with screws installed.

The lid is not that heavy and I seriously doubt the hinge mounts will be ripped from the case in normal use, even over time, unless of course you decide to set your 5 pound roll of solder on the lid while open, but I suspect the radio will tip over first.

Beside the original "Paraset" construction was 'landscape' NOT 'portrait.

Hello everyone. I just joined the group yesterday and received an email that says I have to send this email to be able to send messages to the group. I have been a Ham operator since 1981 and presently hold the Extra class license. My call sign is N1BUS. I have built a few regenerative receivers in my time, mostly for the AM broadcast band. My latest project is a 40 meter regenerative receiver using a 3 part coil cosisting of a main tuning winding, tickler coil and antenna coil. This worked well on the breadboard and I want to build it up permanent on a wooden base.

Okay, but for the photo the club should have put in all the screws; just does not take that long, does it?
I base the comment about the light-duty hinges on my experience with this kind of light-duty storage box.
It’s not only weight, but bounce or impact of fully opening the lid to resting position, that stresses the hinge area.
It’s not one event, but accumulation of repeated stresses that does it.
Yes, i understand the box is an aftermarket item and not designed by the 4SQRP club.
I don’t know what the original ‘Paraset’ was like in this regard, and i don’t want to look up any photos of the actual thing right now.
(I have a couple books with period photos.)
The PRC-5 agent radio had a hinge that could be slid apart to completely disconnect the lid.
I have ordered one of the 2017 Parasets.

27603. "the single tube" for transmit and receive

Yahoo group: regenrx (2016 — 2017)
Date: 2017-01-22 05:26:02 UTC
From: Hubert Miller
Topic: 27603 Message: 27603

I thought i'd mention this, as i (at least...) found it interesting.
Dave Stinson, on the milsurplus group, reported on his restoration a U.S. Army transceiver, type BC-9, dated 1921.
This small portable CW set uses an oscillating detector followed by a couple audio stages. It used a large loop
antenna mounted on the radio box. For transmit, the oscillator B+ voltage was simply boosted from 90 volts
to 170 volts - no other switching executed, i believe. (Fits the 1920s "blooper" epithet.) The output he measured
was about 1 watt.
What Dave found, and what perplexes him at this point, is that on 'transmit', the frequency drops about 15 kHz,
making it nigh impossible to use on the hambands without a pre-arranged contact.
My own thinking was, if you are only using two BC-9 together, they can work even with this t-r offset. I also kind
of doubt the original 01A tube drew that kind of plate current, but i may be wrong on this. So my conclusion is
that the offset is not that great if using the original tube type and not a more modern power tube (triode connected
6AQ5) and that second, the Army used these BC-9 to BC-9 so the offset was workable. I can cite a couple other
later Army sets of the late 1930s that had frequency offsets or did not have a BFO offset so you'd have to tune the
sets to slightly different freqs anyway.

This reminded me of some posts we had a while back about the 'single tube transceiver' but i don't recall any
problem with a frequency shift being mentioned.

27604. Russian regen kit "Mohican"

Yahoo group: regenrx (2016 — 2017)
Date: 2017-01-22 06:24:45 UTC
From: Hubert Miller
Topic: 27604 Message: 27604

Did you see this regen receiver board kit from Russia?
Seems like even after the demise of the big famous kit companies, there's more regen kits out than there has been since the early 1950s maybe.
http://www.ebay.com/itm/282285217927?rmvSB=true

There's 3 videos.
The 40M SSB reception video shows it really needs a metal front panel.
The 20M CW kind of shifted freq a little even with no human intervention - impossible to tell, i think, whether a temperature effect or maybe something inherent,
like backlash effect, in a variable, like the regen pot.
Does not include the air variable capacitor.
Says it's called "Mohican" in Russia. Odd. Anyway this may be the "Last of the Mohicans" even in Russia.

From: Richard
Topic: 27603 Message: 27606

I think the only to work with frequency shift is to re-tune for transmit
and receive. If not, the second station will be twice as far off
frequency from the first station, and no contact. Well, you could use
two sets, one to receive and one to transmit.

Richard, AA1P

Date: 2017-01-22 11:53:34 UTC
From: dulmagedon@...
Topic: 27603 Message: 27607

I have done this a few times. The first was posted and detailed here some years ago. I am sure the photos are still here. The last I built was just last fall when I did my take on the Weskit . Here is how it is done. And PSE note this is how it is done not how it might be done. On the first one I added a small padding cap into the receive circuit enough to cover the shift in tube voltage and consequentially freq. It worked seemingly fairly well but I did not have enough stomp or output to make it a useful transmitter from my place which is some distance from other Cw operators so it worked but if you wish to dismiss it I can live with that. When I built the last I used a seperate slug tuned coil for TX and receive and set each so it would be right on. Then I even went a step farther and pulled a plate from the ganged daul section tuning cap in the RX section and added a bandspread variable with two plates in parallel with that section, normally set about 1/2 way to give the same value as before more or less but also to give me the ability to RIT without changing transmit freq. It couldn't work any better. I can find you if you are sideways a bit up or down or can work you easily if you are right on but can do that without touching my transmit freq. So either method works. BTW where did Dave Stinson post this? It sounds like a very interesting radio. Hartley Regens BTW lend themselves very well to be coming one tube transceivers. On the first one I used a 56 tube and later added a PA which was a audio PA on RX and a RF PA on Transmit. On the last one I used a dual triode with different characteristics BUT only because I wanted a more powerful TX . Nothing would prevent doing it with one as well since only one section is powered anyway. The last is a real fun and practical radio and I have enjoyed using it on 40M quit a bit. The first has been repurposed after the last one was up and running. It only takes one dual gang dual throw switch to effect it. Transceivers are fun projects.

Hi Russ and the group, I am planning to use transistors for it. I had breadboarded it a couple years ago using an audio transformer in the collector circuit to take off the audio. However, after reading some of Walter kitchin's papers I will try using an rf choke and low pass filter method.

Dave Stinson posted all that on the milsurplus group (milsurplus@mailman.qth.net) .
His declared rule, and with good reason for a 1921 antique, is NO circuit modification, so i think he's stuck with it as-is !
I had one of those BC-9 sets back around 1980, but the lack of the large (maybe 5 foot wide by 3 foot tall) loops and the
lack of tubes convinced me that i couldn't make any progress toward actually using it. The instructions spoke about
hand-selecting a tube that would work at that "high frequency" , 3-4 MHz, and that was another hurdle.

For some reason i thought you had solved the frequency offset thing easily but now i see that you actually put quite a
lot of thought into it.

Somebody told me it wouldn't work. My XYL would tell them "Don't say that to Don . It is like waving a red flag in front of a bull." (I heard her tell one of my engine customers that once) I am intriqued by the fact that other then earphones and a regen control here is no real difference in the circuits.(TX or RX) I have a schamtic for a 1920s one here somewhere someone sent me back then. So the concept was not unheard of. I know nothing of the radio you spoke of. I built the POW regen in the birdhouse and could make it Transmit or receive simply by playing with the B+ voltage and the freq variation was not significant but I didnt go from 45 to 90 volts ether. Probably 68 to 90 if memory serves me. The 56 tube one was not real bad but enough to be a pain so I added a padder to it . I had it here for several ears. In fact I think it got repurposed last year about this time as I used the repurposed rig on the Linc Cundall event. The tubes are still mounted on the same base but the regen design has been changed as have the tuning coil and variable caps. It would not be any difficulty to work cross band anyway. Used to work DX that way in the 1980s. When I did the last one the Weskit inspired one I was determined to have a very workable station when done and I do. Depending on the circuit the difference in freq is not necesarily that great and could be in some cases easily compensated for with a gimmick cap (twisted insulated pair) Real interesting stuff to play with. The other end of this extreme is the VHF simple rigs of the 1940s which literally were just glorified supergennies. My No 19 Ws has a 235mcs B transceiver that doesn't have enough parts in to spit. Obviously it worked and on phone too. I would love to see that circuit . I might be tempted to dust of another 01A and try my hand at it.
In my shack a regen is an under powered Hartley or Armstrong and a TX is an overpowered Hartley or Armstrong.

With many thanks to our members, I've received the correct BC-9A schematic (Thanks Dave Hollander):
https://goo.gl/photos/QAiuWy7SsmxbEGmL8

A detailed technical PDF (Thanks Ray Chase):
https://drive.google.com/file/d/0B1zXYo8XYQS8c24yVGViMWM3cFk/view?usp=sharing

And other excellent information from other members.
Our people are the best.
Looking forward to the process of reviving this century-old-warrior.

It really intrigues me to know that when this radio was in use by the 3rd Battalion of the 12th Infantry Regiment, thousands of veterans of The War for Southern Independence were still living.

Here’s a note my friend John, AA7W, sent me:

From: JOHN
Sent: Monday, January 23, 2017 12:51 PM
To: Hue Miller
Subject: Box

Researched some more on that 4-state QRP rig. Looked up the SKU number for the Hobby Lobby wood box(s). Based on that info, you have to buy a three box kit for about $23 to get the small one (7.75"x5.5x3.25), so that is kind of a rip off when you can get individual boxes for under $10.

Going to stop at the new Hobby Lobby store this Saturday and see if there are any better options then buying three to get one.

My neighbor is a wood worker and could easily make better boxes out of Oak or other hard woods. Still, I'm going to get a pine version as an example for him. I would also add the brass corner bumpers that were common at the time.

Dave Stinson has posted about some interesting restorations. In one transmitter, he replaced the $$$$ type 10Y tubes with triode-wired 6AQ5.
As you may know, some old power triodes have really escalated in price, because the “glass audio” fans cherish them.

Dave also was among the first to use those programmable CMOS oscillators to replace expensive crystals in old gear.

One interesting thing you may have noticed is that on the BC-9, the telegraph key folds down from the front panel.
I have a later “loop set” that uses a single type 10 transmitter and 3 type 30 in oscillating detector receiver.
An Army vet who had used the set in training told me that to get additional range, they would use large alligator clips to tap onto the loop
antenna and attach a dipole antenna. This would boost the range from 5-10 miles to about 35, daytime.
As with Dave, i do not have the large loop antenna. He said he would assemble the antenna from copper tubing.

Hue, your friend found one of the problems with the Hobby Lobby distribution. If you go to HobbyLobby.com and search for 662536S (the SKU# for the box we are looking for) you will find nothing! If you search for 662536 it will take you here:

http://www.hobbylobby.com/Crafts-Hobbies/Wood-Crafting/Unfinished-Wood/Wood-Rectangle-Box-Set-with-Silver-Handle/p/25426

If you mail order you cannot buy a particular box out of the set. If you walk into the store you will find that each piece is sold individually but all three pieces add up to the $23.97 price.

What I find odd is that last year Hobby Lobby would have half of the store on sale at 50% off and next week would be the other half of the store. Now it appears to be 30% on some things and 40% on others. If you go to their website you can get a 40% off one item. Since your friend has a local retail store he can walk in there and buy just the 662536 (7 3/4" x 3 1/4" x 5 1/2") small box for $5.99 this week or $3.60 next week or use his online coupon of 40% off one non sale item.

The other thing that annoys me about Hobby Lobby's distribution is that you cannot mail order the item and have it shipped to a local Hobby Lobby store free. Everything comes from their Oklahoma City distribution center even for us here on the left coast.

Hobby Lobby has other wooden boxes too as does Michael's and I am sure many other craft stores or as your friend mentioned it should not be hard to make a box of the 7 3/4" x 3 1/4" x 5 1/2" box for the Bayou Jumper.

Good luck.

Attachments: 1 described; binary payloads are missing from this source WARC

I have a Loop, in fact two of them as I did some loop experiments early last year. I used 3/8 copper tubing. And they are both tuned (variable cap) as well. I would probably use 01A tubes. They are underated and will run at voltages way above specs without a whimper. I use them in my Bruce Kelly AWA rigs.
Funny you mentioned 6AQ5 tubes triode connected . The last 4 in this rig which is a quad four of sorts (with a single tube osc) are so wired. They work well like that.
Dave's claim to fame here is his advice on the most practical way to build a ARC5 replacement AC PSU. In fact I built a similar one for my NO 19 WS and more recently My Collins TCS station as well. Good design easy to execute and works nicely.

27621. 2.5mH Chokes

Yahoo group: regenrx (2016 — 2017)
Date: 2017-01-26 22:24:32 UTC
From: n0sa@...
Topic: 27621 Message: 27621

I just did something interesting (to me anyway). I just finished up building a two tube regen that runs on 12 volts DC. this is a design by Kees Talen K5BCQ . Link at bottom of page.
I had the final product finished except for 3- 2.5mH chokes that I have on backorder form Mouser. I had built a prototype using full size chokes but my final design was for a much smaller radio so I was waiting on the smaller chokes to finish the project. I designed this particular radio for just the 40 meter band so no wideband coverage.
I decided to try replacing the three 2.5mH chokes with three small chokes wound on FT37-43 toroids.
I put 12 turns on each toroid and they measure roughly 50uH in value. I installed them in the radio and it works wonderfully. I can sense no ill effect of using these smaller value toroid chokes. I have built quite a few solid state radios and they all used the same chokes to keep RF off power lines so I figured it might work okay.
At this point I plan to leave the radio as is, as it is working so well. I figure that 50uH is probably enough impedance at 7 Mhz to work just fine. If my design was for much lower frequencies, say the AM broadcast band I may have run into problems, I don't know for sure. Just thought I would throw this out there to see what others have to say about it.

I also used an iron T68 size toroid for the main coil and it works very well also, seems to be very stable and a small footprint.

Some of the projects used a standard Radio Shack 100 uH choke. Your torroid chokes might be an even better idea as their magnetic field is
confined, which possibly might avoid untoward feedback effects.
What were the tubes you used?

Same here. I suppose with a high impedance from grid to ground, there's capacitive conduction from input to plate.
That would seem to be an error in the original schematic.
-Hue

>I don't understand the point of the RF choke on the grid of the first triode. Is it a grounded grid amp, or isn't it?

From: Hubert Miller
Topic: 27621 Message: 27626

Mike, K5BCQ's text comment on that point:
"I wanted the grid of the RF amp to have ONLY the bias level established by the 1K cathode resistor on it, not any potential RF from the ground to "control" the signal, so a RF choke was added. You can also tie it directly to ground or through a x00K resistor but I believe the RF choke is better."

With the grid directly grounded, the grid bias is already ONLY dictated by the 1K resistor anyway. I think with the choke in, leakage and stray capacitance (including the tube socket switch at RF) accounts for the RF getting to
the plate.
You are right. Good catch.
(Is this "nitpicking" ? I don't think so.)

I just tested the operation with and without the choke in the RF amp. The overall gain is about the same but there is more adjustment available with the RF gain pot. It is nicer without the added choke in my opinion. I don't know that much about this stuff so it is trial and error for me.
Maybe I will post a few pics of my radio, it really does a nice job on 40 meter CW as well as SSB.

The value of 2.5 mH seems to have taken on mythical powers I think, just because it was the "go to" RFC for so many projects, but the actual impedance value usually isn't critical. (Of course you don't want any self-resonances in the range of interest). I often use 1 or 1.5mH values with no problem.

In fact, it's easy to make an RF choke that's suitable for most homebrew tube projects. Start with a plastic sewing machine bobbin that are sold in a pack for a dollar or two in the sewing department. Mount it on a small bolt and chuck the bolt in an electric drill, then wrap it full of small gauge magnet wire, and add a wrap of tape or heatshrink. I think the wire I use is 30ga. but the size isn't critical, just use something similar to what's used on the old style RFCs. The Q will not be as high as the pretty pi-wound type, but impedance is impedance, and even 1 to 1.5 mH (which is what these typically come to) will put about 100K in series with the RF signal at 10 MHz, which is usually plenty to keep the RF where you want it.

Bob's observations are right on. The 2.5 mH choke with its four pi-wound, each with a universal winding of Litz wire, sections is an object of utilitarian beauty.

It can be quite satisfactorily replicated in more plebeian form, as he has helpfully explained.

27634. OT: OK, now that I have it, what do I do with it?

Yahoo group: regenrx (2016 — 2017)
Date: 2017-01-29 23:57:53 UTC
From: Phil
Topic: 27634 Message: 27634

OK, sorry about the OT post, but there is a lot of knowledgeable people here. I don't really know where else to ask (maybe build a regen in the case ;-).

I was visiting my neighbor today and he was cleaning out his mobile home as he's getting married and moving out (the trailer is a total piece of junk and will probably be torn down). A good neighbor, I'll miss him, but not the trailer . . .

Anywhoo, he was piling up junk to go to the dump, mostly old 'puters, monitors etc, things I wouldn't bring home for fear of roaches. But I spotted a small electronic looking metal box, about 10x6x9 inches. Very rugged and heavy, I lifted up the lid. Lots of buttons, switches, a gazillion LEDs, two digital displays (one in the lid) and so forth. He didn't know what it is, or even where he got it from. Probably a yard sale or something.

Turns out it is a Phoenix Microsystems Model 5575 T1 MICRO BERT with the 5565 DSO Drop/Insert Lid option (and apparently the battery option due to it's weight). Some quick Google research shows that it is a TelCo T1 line tester. Even though the model number doesn't have the "B", it is apparently the "B" version as it looks like pictures of one (the "A" version is different).

Now the 64,000 Dollar question (remember that show?) is, WHAT USE IS IT TO A RADIO MAN who has a fairly well equipped (even if vintage) test bench??

In other words, can I use it for anything around the shack, other than parts?

TO A RADIO MAN who has a fairly well equipped (even if vintage) test bench??

Answer: none

>In other words, can I use it for anything around the shack, other than
parts?
73 de Phil, KO6BB.

Answer: no. Even then, the parts count you can actually use is pretty low.
It might be some fun to take apart, but it's also tedious and a lot of work.
You might be able to use the power supply,
or parts of it. The power supply probably puts out voltages other than what
your other equipment wants. If you need hardware, i mean screws and nuts,
this will get you a good supply. Depending on how many holes in its carrying
case, the box might be useful for carrying tools or something.

DS1 and DS0 data rates (approx 1.5Mb and 64kB) are pretty near the end of their
history. There is NO market for such test set. If you give it to Goodwill, some
fool will buy it and try to flog it on Ebay, which is a futile effort.

This reminds me, i still have one or two such DS1 Bit Error Rate Tester in my own
storage that i need to compact. I have already taken apart 2 or 3 of them. One
of them had a separate dismountable 15 volt power supply, which i gave away
free at my hamfest table.

At a hamfest last year i sold two huge Sierra 128 Frequency Selective Voltmeters
both $15. After i tore another one apart here, i recovered two high-quality
tuning capacitors, of 400 pF and 75 pF. I wish now i'd kept the two others for
disassembly. This set, although it does work thru 15 MHz, is the size of an
Hammarlund SP-600 receiver, but without a real receiver's features.
The digital test equipment has much fewer usable parts; in fact, hardly any.

And so as I was sitting eating supper tonight and I wondered out loud of my POW radio would run on potatoe batteries. I would need over 100 taters but It would be fun to try. Perhaps when the weather changes and I can do it outside. Meanwhile I may start collecting the required hardware. 105 large copper nails and 105 aluminum nails. Current draw is quite low for the plate etc but the filament may be a bit of a challenge. Still I am curious could it be done. On building it I used discarded batteries which always have some power and kept adding them till it started to squeal. However if it could be run on taters. It would give the project a whole new flavour;>)

blockquote, div.yahoo_quoted { margin-left: 0 !important; border-left:1px #715FFA solid !important; padding-left:1ex !important; background-color:white !important; } Or, use the tree battery, find a nice large tree and all those nails tapped through the bark would give you a potential. And you could still have home fries.

You are right in the sense that each pair would indeed generate power. However, without insulating each cell from the others, there's a sneak path through the conductive electrolyte that shorts things out. That's why, for example, your car battery has individual compartments for the cells.

So, slice up that potato or tree into sections and you're good to go.

Tom

We have here devices called Eco fans that sit on top of a wood stove and run when the stove is hot using the differential in heat to power them. I suspect they are peltier devices or something along that line. Never thought of it before but if they will run a fan they will run a radio. only previous interest I had in them was using a bunch of peltier devices for a sold state air conditioner. Very interesting , alternative energy sources. I heat my home with a passive solar heater on sunny days. It works perfectly . I have a small solar panel keeping my 12sl7 regen heater battery charged. I have tried a jar of vinigar and aluminum and copper electrodes for a battery and it worked fine. So tater power is also of great interest. Always wanted to build a wind powered Air compressor for my shop which immediatley leads to a wind powered AC/or heat pump concept. A multi cell compostor would probably be a decent light use power source. Why didnt I think of this stuff when I was younger and had some zip.

"ABC Exits Shortwave Radio Transmission. The ABC will end its shortwave transmission service in the Northern Territory and to international audiences from 31 January 2017."

Maybe this has already been posted here. If so, i missed it.
This is sad news for me. I have not fired up any shortwave receiver for a while - the only receiver i have on hand, not put away in storage to prepare for a move,
is an Icom handheld IC-R20, and it's a poor substitute for a real shortwave radio. But i had looked forward to hearing Radio Australia again. In the past, going
back to the 1970s, i enjoyed R.A.'s afternoon and late night broadcasts to here on the Left Coast, and using a great variety of receivers, from the 3-tube
Knight "Space Spanner" to ex-military receivers to commercial products both good and mediocre. I will warmly remember the great programming and the music
RA introduced me to.
Yes, i can if i want, listen online now. But a little bit of the magic is gone, now that the program can no longer arrive at my own obsolete, home-built, or classic
veteran equipment by simply bouncing its way across the Pacific.

The withering of AM broadcasting is sad indeed. The dismantlement of transmitters and antenna arrays gives rise to concern. Should, one day, the sun or bad boys cause digital networks to fail, what then?

View on www.pbs.org http://www.pbs.org/video/2365946487/
Preview by Yahoo

at about 5:30 he makes an aluminum-air battery (50 cells) out of aluminum cans, charcoal, seawater, cloth and a little wire. The voltmeter shows roughly 1 volt from a single cell.

Might be useful for powering a solid state regen ?

It was a good show. I happened to see it too. 50 volts would do a tube regen too. They start to work on simple triodes around 38 volts and will stay out of osc mode till sometimes as high as 68 volts. By doing it that way you can make an operational regen without a regen control. Above that you need a pot or regen throttle cap.

well heres a twist......
Zinc sulfate from Greenway Biotech Contains 35.5% zinc and 16.5% sulfur

3 pounds on EBAY costs $13
http://www.ebay.com/itm/192046636849

So then I have to ask if ALL the zinc sulfate sold in garden centers and
hardware stores
contains SULFUR.
Considering the name is zinc SULFATE.

and is it the right zinc sulfate to build this battery:

http://www.learnmorsecode.com/regen2/battery02.jpg

or will the 16% sulfur ruin the intended chemistry of the battery?

Rob,

Zinc Sulfate contains Sulfur, it's a salt of Zinc and Sulfuric Acid.

The percentages of Elements in fertilizers are rated by the weight of
the Element/total weight of the product.
Zinc Sulfate Monohydrate (ZnSO4+H2O) is a compound containing Zinc,
Sulfur and Oxygen Atoms. A Zinc atom is heavier than a Sulfur or Oxygen
atom. I haven't looked up the atomic masses but by the SWAG method the
ratios look about right for relatively pure ZnSO4-H2O.

Guess the time and money I spent on College Chemistry wasn't all wasted ;)

Good morning to the group. Well at least someplace on the web its morning,
According to my much abused copy of Henley's formulas for home and
workshop, 1908 edition, sulfate of zinc is a poisonous white powder, is
used in agriculture, batteries and rat poisons. it is made by reacting
either scrap or powered zinc with dilute sulfuric acid.
I don't know about its use in batteries but.when I was in Mexico we used it
to keep rats under control at our plant. it was quite effective.

Zinc sulfate should be the same thing

That my .2 cents worth, hope it helps.

I have something called a Lufo lamp. You can google it it. It is an oil lamp with a peltie-based generator on the top heated by the flame and a radio in the base. I added a power outlet so it could power other low power devices like my Baygen Freeplay. It works well and is good for emergencies. Too bad they never made made many of them.

From: Rob
Topic: 27666 Message: 27670

I've been buying the modern 1/2 watt carbon resistors from
BANGGOOD.com... 1,000 resistors for $10
at a penny each..... free shipping.

this goldmine sells 1,300 for $28 .. .. which is really means about 2
cents each.

I can live with that price.
I can build a radio with 20 resistors and not blink at the cost being 40
cents worth of resistors.

Live gone are the days of Radio Shack mugging me for a pack of 5 resistors.

WHAT I REALLY WANT tO KNOW IS IF THERE IS ANY REASON TO NOT USE THESE
CARBON COMPOSITION RESISTORS
IN RADIO CIRCUITS?

compared to using the modern TAN carbon resistors
or using the modern BLUE metal film resistors.

considering I NEVER buy any 1/4 or 1/8th watt resistors.
I stick to using large body ...large wire... 1/2 watt carbon resistors....
because the colors don't get lost in the tiny size and I can find them
when I drop them.

Does ANYone sell 1,300 CARBON COMPOSITE RESISTOR KITS for less than $30?

Perhaps I missed something on MOUSER.com but I could not locate ANY
carbon composite resistors there.
So low cost of shipping means nothing there.

From: Russ Williams
Topic: 27666 Message: 27675

All, I ordered 2 of those kits from Goldmine and paid $14 for shipping. There was an option to pay 12.99 for ground shipping. The kits are on the site under Home/Resistors/Resistor Assortments. Yes, the shipping is a bit high, but likely worth the cost given the amount of resistors purchased. I have spent hundreds of dollars at Mouser for specific items, so what the hell? Will report back....

  Does ANYone sell 1,300 CARBON COMPOSITE RESISTOR KITS for less than $30?

Perhaps I missed something on MOUSER.com but I could not locate ANY carbon composite resistors there.
So low cost of shipping means nothing there.

Hi Guys,

I thought I was the only one that was ripped off by Electronic Goldmine. Electronic Goldmine and several other American online discount electronic parts companies are nothing more than resellers for China with a huge markup. Why don't you buy the same thing from Banggood or Aliexpress and cutout the middleman.

If you enter "carbon composition resistor" in the search box at the top of the Mouser page, it will show you the available parts from Kamaya, Ohmite, TE Connectivity and TT Electronics in 1/4, 1/2, and 1 watt power ratings. What you will not like is the price - 1/2 watt values run about 70 cents each in qty 10 and 50 cents each at qty 100.

Better prices can be found at the places that cater to audiopile and guitar amp builders, who like it or not are the only reason tubes and tube-related components are available at all these days. For example:

https://www.tubedepot.com/products/1-2-watt-carbon-composition-resistors

Click on "bulk pricing", which varies by value but averages around 20 cents each. This is just one such source but finding carbon comps for a penny or two each like we used to pay is not likely due to the decreasing demand for composition resistors.

For those looking to stock their parts cabinets with carbon comps the All Electronics grab-bag is a bargain based on current prices for new parts.

I incorrectly referred to "All Electronics" as the source when it should have been "Electronic Goldmine". Sorry for the error.

Also - those who attend hamfests and electronic swapmeets will want to keep an eye open for parts cabinets and "boxes under the table" where I've scored most of my inventory of carbon comps and others. It's luck of the draw but with the declining interest in homebrewing oftentimes you can but the whole works for what the seller thinks the cabinet is worth. I had one offer to "dump those drawers out to make it lighter to carry" but I declined the offer ;-)

I have always heard to use carbon comp resistors on the line neutral to your circuit ground. Supposedly the carbon comp can take the spikes involved. 100K is the usual value.

When R/S announced that they were closing all the local stores I decided I needed to put in some 'bench stock' for when I homebrew something, OR when I repair somebodies radio (local hams only, as a rule I don't do mail-order repairs). While I didn't routinely buy stuff from R/S (too expensive), they were my go-to place for an emergency resistor, or whatever.

I 'discovered' that parts assortments from Amazon was a good investment, and for several months I spent my 'mad money' ordering from them. I ordered an assortment of 1W 5%, resistors, an assortment of 1/2W 1% resistors, and an assortment of 1/4W 1% resistors. They are all carbon film, and every one I tested was well within tolerance (NOS carbon Comp can drift way off value).

I also ordered a number of capacitor assortments (mostly Low Voltage), Mylar, ceramic, 'lytic, you name it, as well as an assortment of 2KV Ceramic disks.

And finally, I ordered some different Solid State assortments (rectifiers, Zeners, Transistors, varactors, FETS, you name it) , as well as a LARGE assortment of 1N400x rectifiers, etc. Yeah, I probably won't need most of the stuff, but if/when I do need something, chances are I have it. So far, when I repaired some radios for local hams, and homebrewed a few things, I've had every part I needed. A lot better than ordering parts in onesies and twosies and paying the shipping. Of course I KNOW that on occasion I'll need to order a special IC or maybe an RF power transistor.

As a side note, If your order is large enough, shipping at Amazon is free. . .

I have tried fabricating a couple of variable capacitors with disappointing results. I used threaded rod with cut aluminum sheets. Here are some key lessons I learned.

- a drill press is mandatory. You won't get decent results with a drill unless you happen to have world class drill skill.

- flatness of the plates is key. If you can't get the plates flat, you're not going to have a capacitor. This is harder to do than you think. Don't buy plate material in a roll, get flat sheets.

- the best way to cut out plates is by laser or a CNC router. A coping saw would work if you sandwich the plates between wood. Least effective is scissors or metal snips. It's much harder to flatten bent plates than to keep them flat.

- this is one of those things where you will build a few before you make a good product. Build a larger one first, either spaced with air or sheets of Mylar. Remember you are likely going to have less maximum capacitance than you want.

- draw out the whole thing on paper before buying materials. Draw every detail and know before hand how you want to make electrical connections, mount the rotor, so forth. It will help out a lot if you don't make it up as you go.

Hope this helps. I'd like to do this more, but good metal is expensive.

Were you to make the rotor shaft from bar stock, it could work provided you use a square stock or something that could facilitate rotation. Soldering brass plates to the rotor is another option.

If you use a non-circular rod, you also need the ability to cut or machine holes which will allow a snug fit on the drive shaft.

I've always used threaded rod with nuts as spacers. Usually I have to use two.

It really doesn't matter about the cost when you buy them in bulk....
1,000 at a time.....
the price with shipping tops out at 2 cents.

What I want to know is WHY anyone would use the brown body Carbon Comp
resistors instead of the tan or blue resistors.

MY interest here is strictly for the vintage look when building replica
old timey radios.
BUT
Is it a bad idea to use these resistors for any electronic reason?

Just in case this is not known...

The folks at midnightscience.com have commercially made 365pf variable capacitors available.
They are more about crystal sets, but have some hobby stuff too.

Anyway, both single and dual gang variable capacitors are available, plus a recently introduced single 365pf with 8:1 reduction!
http://www.shopping-cart.midnightscience.net/t/capacitors

I get a newsletter from them every quarter, and they show up at the QRP conference in Branson each April.

Carbon comp resistors produce higher noise level. This may not be important in radios, particularly vintage ones. However, it makes a big difference in hifi audio equipment. That said, there is a cult around carbon comp resistors and some vacuum tube audio guys like to use them.

I think it depends on the application. Carbon resistors are
non-inductive and are useful as "stopping" resistors in audio circuits,
and parasitic damping resistors in radio circuits. (same thing) They
also age badly. Other than that, I think the newer resistors are better.

27692. Re: Variable Capacitors / Condenser

Yahoo group: regenrx (2016 — 2017)
Date: 2017-02-10 01:50:07 UTC
From: johnhutnick@...
Topic: 27678 Message: 27692

Go to the Regenrx2 group and look at photos under my name -- johnhutnick. There are two variable capacitors that I made. One was made with pieces of tin can tops, threaded rod and nuts, plywood ends. The other is a large, flat sliding plate variable on wood block with tinplate sliders.

27693. Re: [regenrx] Carbon Composition Resistors verses new carbon verses metal film resistors

Yahoo group: regenrx (2016 — 2017)

From: Tom Lee
Topic: 27666 Message: 27693

They definitely produce more "1/f" noise than do film resistors, with the noise increasing with dc bias current. Since it is 1/f noise, it not only affects audio/baseband circuits, it also pollutes local oscillators, where this noise converts into noise near the carrier. So, it can still degrade RF circuits through this mechanism.

Just posted this in a sister
group, and hoping maybe posting it
here might bring some results.
Thanks Guys
Bill

>>> Clip

Greetings Electron Benders
Been looking for a book that is out
of print. It’s Surviving Technology by
Bruce Vaughn NR5Q. Tried Amazon,
Ebay and the Inter-library loans and no go.
Tried Electronic Radio and I can’t seem
to find a copy.
I would like to beg borrow buy or steal
a copy of this book. It’s main point as far
as I know is to get the most out of a regen.
Thanks for the Bandwidth Guys
73 fer now
Bill KE9XQ

Try contacting the editor at this publication, they were suppose to sell
it but I don't see it listed. However the title is "Every Blade of Grass".

Sorry I forgot the link;

I live in Joplin Missouri, USA and in the late 1800's, both Lead and Zinc were discovered here. The last mines shut down around 1970. It was labeled as the Tri-State Lead and Zinc mining area, and I was told that it had the distinction of being the 3rd largest supplier in the world in the early 1900's.

Anyway, the mineral museum has small chunks of "galena" mined from around here available. I have been able to harvest some small pieces from old tailing piles.

I have some here.

If they have Galena then they have lead deposits also, Galena is made
from lead.

Building a variable capacitor is no-sweat.
Whether linear or logarithmic is secondary.
Merits an online peek at WW2 POW ingenuity...

Galena will, however, be the new rare metal if Father Sun
(or Badboys) burps and wipes out our chip-enslaved world...

Michael UK

PS: Smug, I have a Galena sugget from a SK neighbour -
and a few vintage tubes...

I did check this month's issue of ER on your behalf, but it is no longer listed in the books section.

You should try contacting the ER editor ray@ermag.com.

Good Luck!

Bruce Vaughn is a silent key now, so it's not clear if his book will ever be reprinted.

Regards,

John

Seems to me that there is a used book store called albris. So maybe
albris.com will connect.
Any university town might have used bookstores too.

Do a search for used book. It was Alibris not albris. Also try abebooks.

I think it more interesting to build the parts in my shop than using off the shelf parts
I even looking in making head phones this part may not happen
so any thing you may and ideal please let me know
I was 4 years and just did have time as my wife and self had little work on our home and work got the way too. Starting whit new roof and work our way down

here my group web page https://groups.yahoo.com/neo/groups/southbendlathe9/info
https://groups.yahoo.com/neo/groups/southbendlathe9/info

That's interesting Jim, as I also live in a former lead mining area here
in the Driftless Area of NW Illinois, where lead mining at Galena IL
made it a much larger settlement than Chicago in the early years.
There are tailings pile visible near the tiny community of New Diggings
just across the Wisconsin state line and I've wanted to do a little
prospecting some time, if I could get permission or at least not get
shot at ;-)

I have made a few. You probably want pro looking ones and I was making them from garbage for the POW Radio Build a Shortwave one tube regen built totally from garbage dumb findings. So I used soup can lids. Threaded rod does Not work well because it does not have good quality thread. Fine thread bolts work well. When cutting or drilling the plates sandwich them between wood blocks which are bolted together and cut or drill them all together. That gives better edges and allows for no bending. large washers can also be used for plates if cut just above the centre hole also bolted together between blocks of wood. (Plywood for instance) End Good quality fine thread bolts and nuts should be used and washers can be used to get the initial offset between stator and rotor. If two nuts are interlocked (tightened) even with a washer between they will not come apart by themselves many more are just that much better. I used the normal thickness of the nuts to give me the spacing. Addding a locking agent to each nut on the rotor shaft gives just that much more saefety although I have had no problems. There should be some photos here of the POW regen in my albumn. That is for a conventional variable. A slider type can also be easily made with some hardwood and two plates of flat metal with ends cut on a slope. the slope cut ends go to the same side so the capacitiy rises slowlly and smoothly as the moveable plate is slid over the fixed plate. Just two ways to do it.

Excellent idea! It's nice to know Bruce's site is still up.

Keep in mind that the book is not "all about" Regens. It's got lots of great stories about his teenage years as a radio enthusiast/ham, his WW2 experience, and his long career in radio/TV sales and servicing.

The book ends with detailed plans for Bruce's Ultimate Regen. (Which I have not yet built).

This was just FYI. It's a great book and very highly recommended, but if you're expecting a book entirely devoted to various Regen projects, you may be disappointed.

Regards,

John

REALLY appreciate
everyone’s input on getting the
book and it’s contents. Sounds like
a great book all around. I did not try
his family, but I did try Amazon, and
was surprised someone found a copy
there, as I looked more then once with
different search properties. Tried Ebay,
Abe’s and Electric Radio and no go, my
posts here and a sister group led me to
a kind gent that sold it to me and should
mail it out to me probably Monday sometime.
Thanks Steve WD8DAS :) REALLY
appreciate this! :)

Again thanks to all replies both on list here
and off, much appreciated :)

27720. Re: [regenrx] Surviving Technology book by Bruce Vaughn found

Yahoo group: regenrx (2016 — 2017)
Date: 2017-02-11 03:42:54 UTC
From: Kirk Kleinschmidt
Topic: 27714 Message: 27720

I have some letters that Bruce exchanged with me from the early '90s that had several of his regen designs and a bunch of charming personal quotes, etc. In my QST days I edited several of Bruce's articles, and he sort of "befriended" me in "wise elder counsels upstart whipper-snapper" sort of way. :)
(I haven't yet built Bruce's Ultimate Regen, but I did build a nifty one from the 1929 Handbook with much help and encouragement from Dave, W9VES.)
When I find Bruce's stuff (just moved), I will share them with anyone who's interested. He was a real class act.
Also, if someone can put me in touch with the copyright holder, be it Bruce' estate or the last-known publisher, I'd be happy to republish the book in Kindle, Createspace and/or Lulu formats.
I'm doing that stuff for a revised edition of Stealth Amateur Radio anyway...so what's one more? Especially one that's essentially "camera ready?"
I have been thinking about republishing certain out of print radio books (with contracts, permissions, copyrights, etc), so if you know of other niche candidates, please let me know.
Thanks, and 73,
Kirk, NT0ZRochester, MN
My book, "Stealth Amateur Radio," is now available from www.stealthamateur.com and on the Amazon Kindle (soon)

Galena can be made by melting good lead and adding a small amount of sulphur as it cools. You have to experiment to find the right amount.

I don't know what happened to my comments, but you can make galena by adding a small amount of sulphur to molten lead.

☐

Yes,

Galena, also called lead glance, is the natural mineral form of lead sulfide. It is crystalline and shiny. Pretty to look at, and used in early radios. If you have an Alfred Morgan "The Boy Electrician" or an early Boy Scout Wolf book, galena is used for the detector in the crystal set.

Some crystal radio experimenters have reported success with chalcopyrite, regular pyrite pieces, and even rusted razor blades. Pyrite is far easier to find than putting effort into melting lead and adding sulfur.

From: Hubert Miller
Topic: 27614 Message: 27724

I printed out the partial manual pages. The earlier version did not use the plate dropping resistor. When keying the transmitter "on", the key grounds the B-.
For receive, you have to close the key. The key also has a "third leg" to short the headphone to ground, to limit audio pop when keying. The bias control was to crank the oscillator level down to minimum for receiving, or up to 8-9 mA for max range, apparently. So with this version, SCR-77-A, you have no frequency offset at the price of problems with nearby sets maybe overriding weak signals.

There are no clues about operating the version Dave has. The netting procedure solely consists of calibrating the receivers of sets to one set defined as the master set, done at one setting. If the other channels of your outstation set do no line up with what the master station defines as the channel number, you are to mark on pencil on the dial the actual point where that defined channel is to be found.

I suppose with the later BC-9 you could maybe "calibrate" the set by marking with pencil the setting for transmit frequency. Think so?

With many thanks to our members, I've received the correct BC-9A schematic (Thanks Dave Hollander):
https://goo.gl/photos/QAiuWy7SsmxbEGmL8

A detailed technical PDF (Thanks Ray Chase):
https://drive.google.com/file/d/0B1zXYo8XYQS8c24yVGViMWM3cFk/view?usp=sharing

And other excellent information from other members.
Our people are the best.
Looking forward to the process of reviving this century-old-warrior.

It really intrigues me to know that when this radio was in use by the 3rd Battalion of the 12th Infantry Regiment, thousands of veterans of The War for Southern Independence were still living.

The simple basic tank circuit with earphones and a cap and one diode in the loop works well everytime. Occasionally variations appear to work better but more and more I think it is in ones mind as one finds they keep going back to that old reliable design. You will have to decide for yourself. Built a normal circuit and then go nuts with one. If you find yourself reaching for the normal one more then knot you will know you came to the same concluson as I did. There is a lot to be said for easy to build , always works well designs.

Certainly you will hear stations with this approach. But the question was "best". What's best for one person may not be best for another, do you mean highest performance, or simplest design, or all homemade parts? Do you want to equally accommodate differing antennas, grounds, and headsets? So Coupling the antenna to the tank with a separate coil, Or tapping the antenna or detector up or down on the tank might produce louder signals. How about one of the Alfred Morgan double slider tank coil sets, maybe one for the antenna and one for the detector… or adding an S-meter… all passive Fun! There's lots of possibilities for experimentation, so have a look at the various designs out there and you'll have plenty of ideas to try! One of the Midnight science Crystal set society books is good starting point. Good luck, let us know how it goes! Regards, Mark -----Original Message----- From: Rob roomberg@... Almost any circuit will work if one has a good antenna and ground. The question is how well - how good is the sensitivity and selectivity. Since there is no amplification and only loss, it is important the signal power picked up is maximized (good antenna and ground) and losses minimized. All circuits beyond the very basic try to minimize loss - some more successfully than others. If you live in a metropolitan area you will likely pick up at least one station easily and it is quite possible that you will pick up several more and the problem will be tuning to only the one you are interested in. However, if you are in the boondocks like me with no powerful stations nearby, the problem will be in getting a good signal and minimizing losses as much as possible. If you select the right circuit and the right components (all air variable capacitors are not the same - ones that are silver plated, have ceramic dielectric and multiple brushes are required to minimize loss; use litz wire for the coils) and have good antenna and ground you can not only get many stations, get very good selectivity and listen to stations 500 or more miles away even when one lives in the boondocks. The ones I like are circuit #77 (http://makearadio.com/crystal/77.php), circuit # 78 (http://makearadio.com/crystal/78.php) and the loop crystal radio (http://makearadio.com/loops/loops3.php). You will also need a good pair of high impedance headphones - if "sound powered” it is even better.

Raj

27739. Question about Kitchin Regen from 2010 CQ Magazine

Yahoo group: regenrx (2016 — 2017)
Date: 2017-02-12 19:59:54 UTC
From: kc2siz@...
Topic: 27739 Message: 27739

I've started building Kitchin's 2010 "high-performance regen".

An article from CQ Magazine, which contains a schematic, is in the files section.

There were a few corrections made to this article after it was published. The corrections all concern the audio section. They include the value of R11 (should be 2.7ohms) and C22 (should be ceramic .1 microfarad). However, I also notice that the value of of the electrolytic cap C20, listed as "5", does not look right.

Does anyone know what the correct value should be?

Thanks,

Steve

Hi Dave, good luck! The antenna, ground, and headsets together are probably more important than the radio itself. Spend at least as much time at those items as the radio and I believe you will be successful. Regards, Mark -----Original Message----- From: davesmith1@... 27745. Regen osc freq shift in tube circuit?

Yahoo group: regenrx (2016 — 2017)
Date: 2017-02-15 21:15:13 UTC
From: Hubert Miller
Topic: 27745 Message: 27745

Please give me your opinion on this.
Imagine a tube oscillator (maybe even a regenerative receiver) oscillating at a minimum level, with a series
resistor in the plate dropping the B+ for regen control. At this point, B+ is 45 volts. Then imagine turning
this control pot down to minimum resistance so the circuit oscillates at the maximum and the tube has
the full 120 volts on the plate.
The frequency will shift, right?
And in what direction?
I know - impossible to quantify - but can you give an approximate figure for the frequency shift?
I know this is difficult - assume a high-C, pretty stable circuit.
thanks-
Hue

From: dulmagedon@...
Topic: 27745 Message: 27746

Again . Been there done that Yes it will shift some BUT the freq is mainly determined by the tank design. It is nothing to build a correction Cap into the circuit that is switched in and it could be on TX only for that matter. I now use though the band spread cap to cover this designing it so the cap is on freq at centre positon so I can go up or down. I have built them with one tank and also with a coil for each but same cap as well. HOWEVER. IF you go from 45 to 120 volts perhaps but if you went from 68to 90 volts which is perhaps more realisitic you will find the change very minor and of no significance. Every regen can do this as it with no modes BTW. At least any that have a well designed regen pot control which can enter oscillation or go below it with ease. The POW set does both Rx and TX simly by adding voltage. The DN-1 does it with seperate coils and the original transceiver (56/58)did it with a correcting cap. I am not making this up. have two working as we speak. Wanna listen on 40m?

27747. Re: Regen osc freq shift in tube circuit?

Yahoo group: regenrx (2016 — 2017)
Date: 2017-02-16 12:23:29 UTC
From: dulmagedon@...
Topic: 27745 Message: 27747

Directly below the red spot that is beside the ARC5 is the original one I built. it was at first simply a 56 tubed hartley regen that would transmit. I switched in a pot and earphones on rx and bypassed them on tx. If it had a problem it wasn't areal powerful rig. later I added a Pa which was audio on rx and a PA on TX . This added a level of complication that took the fun out of it a bu it although the PA would affect the freq enuf to eliminate the pull. Also with a regen , if it was dead nts on the same freq as the TX you would not get the proper note so a small offset say as high as 1000cylces or one KC is easliy tolerated.
Perhaps a better way to think is can you take saya hartley self controlled osc and make it receive. (YES)
In about 1922 there was a circuit published that did both and someone sent it to me when I was exploring this same principle. I went thru all the questions and doubts as well but decided just try. It turned out not as difficult as I was led to believe. I hope you find one of build one as it is an interesting subject. To take it from iffy to workable is so easy it can be done in minutes. and by several different but excellent methods. I still have two such devices and am trying to hold back from building another after reading some of your threads.

From: Hubert Miller
Topic: 27748 Message: 27748

On another group we were discussing a 1921 Army transceiver which uses a single tube in the RF. The tube plate goes to an audio transformer and then to the 2 audio tubes, and the tube runs at around 60 volts. On transmit, a key shorts across the audio transformer winding and the B+ is boosted to 125 volts. The owner of the radio reported that on transmit the frequency dropped 14 kHz at 3700+ kHz, 80 meter band. We were all puzzled by how this could be, and how anyone could actually use the radio.
What was discovered was that - apparently – the chokes and capacitors isolating the the tuned circuit and RF tube plate from the rest of the circuit (audio transformer, dropping resistor, and plate current meter) was not totally effective, so the circuit “saw” other reactive components. Strangely enough, across the 125 volt supply, the bypass capacitor had to be carefully chosen, a value somewhere in the range of 300 pF, and this brought the receive and transmit frequencies close enough together that the set is usable. With the factory-design part, the frequency shift was about 3 kHz.
No one has yet, i think, explained why the B+ bypass must be so carefully chosen.
And just why adding capacitance here RAISES the transmit frequency.
But one fellow commented that the design had to be “empirically arrived at”, and i think we all agreed heartily with that. In this circuit, increasing the B+ bypass capacitor to what you might think was a proper or better value, made the transceiver totally unusable!
So that’s why i asked. I learned from the replies that compared to this circuit’s operation, the frequency shift due to the tube’s operating point is a minor effect !

Date: 2017-02-18 08:27:19 UTC
From: Hubert Miller
Topic: 27750 Message: 27750

I was looking at the manual for the Marconi 730, a 4-valve regenerative receiver tuning 15 - 26,000 kHz, at
http://marconitype730vintagecommunicationsreceiver.itsupportsolutions.co.uk/wp-content/uploads/sites/3/2016/06/Marconi-Type-730-Marine-Communications-Receiver-Service-Manual.pdf
(and many thanks to the person who published that.)

I noticed that the receiver seems to date to 1935, with circuit drawing updates in 1940, after the U.K. was already at war.
Also particularly interesting is the 'Model 763 Buffer', an untuned RF isolation amp, which has a drawing dated 2-1941. I thought it was interesting that this accessory unit was added on much
later and well into the European war.

Topic: 27745 Message: 27751

In this vein I took my twin 26 regen and using a long clip lead bypassed the regen pot, earphones and plate circuit resistor. Shift was 19khz measured on my digital rx. Pretty high although 1/2 that is probably because of the 19 inch clip lead so probably 9 to 10 if I used a short one. Then I went to my 6sl7 regen which is throttle cap controlled for feedback . Surprisingly it is very easy to use a a tx with no significant freq shift. IT wouldn't be great for long distance but nearby coms would be easy. Onthe frst one I used a miniture ceramic ap in the rx tx switch to pad the tank and keep it in the ball game. I may try build another with a 201A with that intent and see what i can do when building with that in mind but with a pre 29 tube.

Akso your project subject Ibeleive used a loop for both antenna and tank. A big coil which has aoop is has usually a very high Q. the higher the Q the better the control . for instance in a TNT transmitter there is the dominant Q effect where the large plate tankcircuit takes control over the small low Q grid circuit despite its roll on determining gneral freq and so the larger Q is always the boss in LC circuits. A loop would have a very good Q I would think and so would be not unrealistic to think of it as large and in charge which may to some aspect limit the swing some as well.

Topic: 26864 Message: 27758

Here I have two schematics of detector stages. The uppermost one is an infinite impedance detector T2 which is preceded by a bootstrapped emitter follower buffer stage with T1. That buffer stage is very important when this circuit is used together with a regenerative stage (Q-Multiplier), by using a buffer stage the tank circuit sees a constant input impedance. When the detector stage T2 would be directly coupled onto the hot end of the tank circuit, impedance increases caused by going into oscillating of the Q-Multiplier stage cause nasty regeneration backlash.

In the lowermost one the buffer stage is followed by a full wave detector stage with biased diodes D1 and D2. When a connected Q-Multiplier goes into oscillating, D1 and D2 will conduct more, decreasing their input impedances which is reflected back to the base of T4. That makes regeneration control more smoothly.

In both schematics these base stopper resistors R4 and R15 are crucial, otherwise the emitter follower buffer stage will parasitically oscillate because of the intrinsic base-emitter junction capacitance and stray capacitances between emitter and ground (Colpitts topology).

Yesterday I dragged out my hb solid state 80M station. It consists of the slugabsorb regen (slug tune fixed cap) and a version of bascially the sardine sender. I gave the regen its own battery , (inside 9 volt) The sender had quit and I had looked it over but not seriously. Eventually I found a sorted Zener that was killing the power to the osc, I made some other repairs as well. This Tx has been here so long it is starting to get some war wounds from repairs and experiments so this is probably its last chance. I manged tho to get it going although I dropped the crystal on the floor and can not yet find it. I grabbed another and had it on air for a bit late last night. I am at heart a tube man but it is good to keep practiced on the SS stuff as well. The slugabsorb
still works nicely on both SSb and Cw. A joy to run.

This is what i would call a “sketch”. I would like to read more about him but apparently a longer more detailed biography of him does not exist.
I think it’s very interesting how a manufacturer of very high-end very expensive receivers in the latter years was producing bottom-end ham radios,
including regenerative receivers, and this equipment was not mechanically very impressive at all.

Hue, have you read this article?

http://soldersmoke.blogspot.com/2011/09/mcmurdo-silver-man-with-knack.html

It's perhaps as detailed as anything that was written, unless there's a more complete biography that I haven't seen. McMurdo Silver was best known for his extensive writing in the radio magazines and for the Masterpiece line of top-end receivers than for the hobby-level test equipment and ham gear that came later. However I did get to see examples of the latter at the Jonesborough get-together last year and these simple entry-level gear had some clever features. (I just didn't think they were $400 clever!).

But most radio hobbyists from the 30s were enthralled by the rivalry between Silver and HH Scott, which became rather bitter as it played out in the pages of the magazines and ads. Scott considered himself to be a craftsman of the finest radios, whereas upstart Silver touted superior performance and visions of being the largest radio manufacturer. You could say that vision was fulfilled - by 1920 the Silver-Marshall plant had the capacity to make 1000 radios per day. But Scott prevailed in the end, as Silver declared bankruptcy in 1938 and Scott bought what was left of the company. Silver died in 1948 at age 45.

My first boss, George Risk, who started Dale Electronics in 1950 (now part of Vishay) knew all of the pioneers from the early days, having grown up in Cedar Rapids with Art Collins, worked for DeForest in Chicago, and socialized with Leo Meyerson as a fellow businessman in Omaha. I don't think he knew Silver well, but through trade associations, as he always said "it was a small club back then", and when you attended trade shows you'd meet most of the principals in the radio business. I remember he referred to Silver as "Mac" and the feud he had with Scott, which as a fellow "promoter" made both companies prominent in the industry.

From: dawmast@...
Topic: 21752 Message: 27777

Here is another regenerative receiver with an interim RF amp stage between the Q-Multiplier and a diode detector stage. It follows the same approach as the GlobalSpan regenerative receiver at
[url]http://www.nutsvolts.com/magazine/article/the-globespan-world-band-receiver[/url].
But I use a differential pair type Q-Multiplier (T1, T2), in stead of using a Colpitts one, and a cascode RF interim amplifier stage (T4, T5) before the full-wave diode detector (D2, D3). T3 is an emitter follower buffer stage which avoids excessive loading of the Q-Multiplier stage by the cascode interim amp. stage. Advantage of using a cascode amplifier stage is its much wider bandwidth, compared with single BJT RF amplifiers. And because of that I can use general purpose BC549C BJTs in the cascode stage, in stead of using RF BJTs. By using a differential pair type Q-Multiplier I only have to use two-terminal coils for L1, which makes band switching much easier compared with coils with feedback taps and/or tickler coils. L1 can be a medium wave ferrite rod antenna, or a loop aerial for on short wave.

Circuit diagram:

For soft regeneration control, stability and high gain, the Q-multiplier stage should be built according this complicated block diagram:
https://groups.yahoo.com/neo/groups/regenrx-simulations/photos/photostream/lightbox/618138320?orderBy=mtime&sortOrder=desc&photoFilter=ALL https://groups.yahoo.com/neo/groups/regenrx-simulations/photos/photostream/lightbox/618138320?orderBy=mtime&sortOrder=desc&photoFilter=ALL
The oldest improvement of primitive Armstrong‘s invention in direction of this block diagram, is the „gridleak circuit“ (clamping circuit) consisting of 100pF capacitor and 1Meg resistor in the tube circuit. The "gridleak" is not invented by Armstrong. At the following JFET Q-multiplier stage, the clamping is formed by R1 and C1:
https://groups.yahoo.com/neo/groups/regenrx-simulations/photos/photostream/lightbox/196033955?orderBy=mtime&sortOrder=desc&photoFilter=ALL https://groups.yahoo.com/neo/groups/regenrx-simulations/photos/photostream/lightbox/196033955?orderBy=mtime&sortOrder=desc&photoFilter=ALL
R2 with small resistance is used in this circuit to prevent VHF oscillation. Note that your Q-multiplier stage has no clamping circuit. Since a stable Q-multiplier has very high gain, a buffer stage (follower) only is enough for correct demodulation.

Q-Multiplier circuits built with BJTs don't need any clamping circuit. The relatively large emitter resistor provides enough negative DC feedback to stabilize its operation point. The differential pair type Q-Multiplier also has a smooth regeneration control by itself.

This is a photo of my 2 transistor regenerative receiver I made a few years back. The photo did not come out too clear. I originally built it to give to a charity yard sale hoping they would sell it for $10. As it turned out the person running the charity liked it himself and bought it putting his money to the charity. My intent with this radio was to show young people that you do not need expensive parts or equipment to build something. It uses a bottle cap for the regen knob, parts of an erector set to mount the controls, wood screws for the connections, and build on a piece of wood . The regen stage is an Armstrong type and the audio is taken from a transformer in the collector circuit.The regen control is a 1 k variable resistor in the emitter.The detector feeds into a 1 stage audio amp with a transformer output. I will have to find the diagram and post it.

Built a 40-meter band copy of AA7EE's "Sproutie" regenerative receiver. Made mine for only the 40 meter band with a fixed coil vice plug-in's. The performance is quite remarkable. A companion transmitter is brewing in my mind.

You can see a description (PDF) and an audio recording (MP3) at files/KI4IO
https://groups.yahoo.com/neo/groups/regenrx/files/KI4IO/
https://groups.yahoo.com/neo/groups/regenrx/files/KI4IO/

Kudos to AA7EE! See the article on his web page. It's worth a look at:
https://aa7ee.wordpress.com/2014/08/21/the-sproutie-a-general-coverage-regen-receiver-with-plug-in-coils/ https://aa7ee.wordpress.com/2014/08/21/the-sproutie-a-general-coverage-regen-receiver-with-plug-in-coils/

Thanks Duncan, I was able to find it online and copied the pages. I'll keep it as reference for a future project. I may not have the tubes called for but most likely substitutes can be used.

Nice catch amigo Rob !!!

Probably you were picking up one of the 4 frequencies we are using on the 49meters or 6 megaHertz international broadcast band... 6000 and 6060 are beaming to the East Coast of North America .... 6100 to the West Coast (we call it the Pacific beam that is also heard in Hawaii and Japan) and 6165 is beaming to Central North America, (the Great Lakes)

Please note that Rob has provided a nice printed circuit board design that will make possible a better looking receiver than one using point to point wiring.

Anyone on the list remembers a thread about the diode detector of the Kitchin regenerative needing a load resistor ?

73 and DX

A very happy Arnie that at three thirty in the morning just starting my broadcast day (I do the morning show for Radio Progreso national network) received Rob's report !!!

Thanks, I was able to download it and view it in microsoft paint. The separate detector reminds me of some transistor regens with a diode detector on them.

27810. Kitchin 3 fet regen

Yahoo group: regenrx (2016 — 2017)
Date: 2017-03-29 11:31:11 UTC
From: SHARKFINGUY@...
Topic: 27810 Message: 27810
Attachments: 3 described; binary payloads are missing from this source WARC

I made a version of Kitchins 3 fet regen based on the one in the 1995 handbook. I have attached photos of the front and inside and schematic. The schematic has green lines through the parts not used and the substitutions written in. I didnt have all the exact parts so I used what I had. I wish I had used a larger box with a longer front panel but was limited by the wood at hand.
The detector is very stable and the regen control works smoothly, but the audio output level is low. A 3 stage audio amp with a gain of 300 was needed to boost the signal. I then fed the audio into a small amp board consisting of a 2n3904 preamp into an lm386 which I screwed onto the right inside corner. This final audio section was put in after the photos were taken.
My plan was to have a 40 meter band receiver but it tunes from just below 7mhz to just under 14mhz. however it still tunes nicely and can receive ssb signals with good clarity and stability. I still need to make a dial for it and label the controls. I may change the tuning knob to a round one and put a wire on it for the pointer. An old clock hand would make a good pointer.

Hola amigo !

Needless to say you made my day with your two thirty in the morning report of my Dxers Unlimited show:

You are right, even a simple and lower cost, easier to find switch one pole two positions, can replace a costly potentiometer as an effective volume control.... My advice is to experiment with the resistors values to optimize the way the volume goes up and down...

You can make use of the 1N4007 silicon power rectifiers found at zero cost on the boards of the CFL lightbulbs... using them as variable capacitors... the way they are built makes them work as solid state capacitors that change with the voltage applied, so you end up with a wonderful FINE TUNING CONTROL, as required for listening to single side band , CW and digital modes .

You buy transistors by the thousands, and I collect the non functioning CFL lightbulbs by the hundreds, then patiently desolder all the parts, test them and finally re'use them at zero cost.... also do the same with old computer monitors , fax machines , motheboards..UPS units etc, and reuse everything that can be recovered, including nuts and bolts HI HI !!!

I do not remember the value of the diode load resistor , but I presume that it goes from one side of the detector to ground... Maybe at the regen list someone will remember about that thread...

One thing to try out, to generate still more interest among the boys and girls, is to try to make the Kitchin receiver to work on the AM Broadcast Band...there are two approaches possible: one to use a ferrite bar to wind the tuning coil and feeback coil, and the other is to wind a big coil on a PVC pipe former...like the ones I use in my diode detector radios...

Congratulations on your contribution to a better world by making the young generation learn about radio... I try to do exactly the same here !!!

73 and DX

Rob, the floating diode *can* work, although it looks unhappy
in the schematic. It probably works because of micro-leakage
in lieu of diode termination. It was used in NA5N's Pipsqueak
and the Desert Ratt-3 receivers. Experimenters either report
good results or no results :-) It would seem that layout and
the chosen germanium diode determine the eureka effect.
The circuitry should be built dead-bug or Manhatten pad style
on a copper board with short leads. A PCB can be counter-productive.

Try different germanium diodes - not all are the same! Silicon
diodes will not work. A one meg or higher resistor, or a second
Ge diode, from between D1 and C4 to ground might help in extremis,
but would reduce sensitivity, a particular merit of the design.
Search Kitchin and floating-diode online; there are lots of postings,
some conflicting. Tinker with it yourself before unveiling it
to expectant scouts. You might decide to adopt a different design
to avoid disappointment... Keep us posted!

This looks like a different Kitchin design, not the "floating diode"
one published in the September 2000 issue of QST. Good to know
it performs well! The floating-diode circuit was innovative,
offering high sensitivity with simplicity. There are three
groups of humans : those who think it's brilliant, those who
couldn't make it work, and those who have never heard of it :-)

Yep..... the experiment continues.....
I know you recycle salvage your parts.
I would do that here if I couldn't buy parts.

My goal is to make something for the kids to learn about short wave radio.
Our local broadcast radio is full of worthless commercial broadcasting.
Nothing as fun as hearing your DX reports.

RE: A PCB can be counter-productive

WHY!???

I had all sorts of stray capacitance issues when I built the 716 regen
with WIREWRAP
http://www.learnmorsecode.com/716/716.html
so graduated to etching solid PCBs for all following radios and getting
consistent results.

and
the goal is to kit radios for scouts so I won't be having newbies doing
dead bug radios.

Rob, the floating-diode design is somewhat temperamental.
You could design a PCB, but might have to try a
few different layouts to find one that allows
stable performance. I would avoid wire-wrap.
Dead-bug or Manhatten pads make it much easier
to group components close together with short
leads. Dead-bug in particular facilitates
rearrangement of components ad hoc. If you
find a stable dead-bug layout, you could
duplicate it with circuit boards with
copper cutouts.

I am beginning to think that the floating-diode
design may not be idea for your purpose. There
are many other proven and easily reproducible
regen designs you might wish to look at.

Rob, I would suggest you peruse the group files.
There are many tried and tested regen designs on file,
including not a few whose simplicity and reproducibility
would match your scouts' requirements. You are the
best judge of what would be most suitable!

Please keep us posted!

Dear amigos !

Rob is right.... a well designed printed circuit board aimed at beginners requires wide copper tracks and large pads... Those boards are also very good for oldtimers that no longer can hold the soldering iron steady enough to avoid bridging nearby tracks.

My direct conversion 40 meters band only receiver is done on such a type of circuit board design criteria. Some of my not so friendly friends tell me that I waste a lot of circuit boards area, and my reply is, that beginners receivers are to be built by beginners and in case something goes wrong, beginners are to be helped by us the more experienced experimenters..

My Super Islander 40 meters receiver module is not intended as a project for a first time attempt for assembling a radio... it requires some mechanical abilities in order to produce a really stable VFO, that is essential for the project to work....

That is why I second the motion in favor of amigo Rob's regenerative low parts count short wave radio... At least in North America you can pick a few stations at night within the frequency range 4.7 to 10 megaHertz... with a special emphasis on 5000 to 5100 kiloHertz and 5.9 to 6.2 megaHertz

Topic: 27811 Message: 27822

I've been down the dead bug path and also Manhatten.... and island
pads..and circle cutters...
tried them all
http://www.learnmorsecode.com/help/cwpmosfet2preamps.jpg
http://www.learnmorsecode.com/help/cwpmosfet.html

but none of these quickie construction methods is good for newbies.
Especially first timers with a soldering iron.
I even tried using Fahnestock clips:
http://www.learnmorsecode.com/help/TWOdiodesBB4.jpg
http://www.learnmorsecode.com/help/xtal1.html
which proves we can build anything... but isn't real good for newbies.

I have no problem etching PCBs in my kitchen.
I don't do tiny traces on account of my ailing vision..... so my
artwork looks medieval compared to
industry standards..... 1/8 inch wide traces......
http://www.learnmorsecode.com/regen/00kitreg01.jpg

But there are advantages to such huge traces.
Any mistake or modification can be just another drilled hole away from
being cured.

Folks, we are confusing issues here.

A wide-track PCB would be ideal for beginners building
a stable and proven design.

However, a temperamental design whose success depends in part
on layout and components may not be the best option
for beginners. If selected however, it would need careful
tried and tested design of the PCB and of layout and
selection of components, in this case particularly
of the unconventional germanium "floating diode".

One of the uncontentious alternative designs in the group file
section might therefore be more appropriate for the task in hand.

That is the crux of the issue with the Kitchin design.
Sometimes it works brilliantly, sometimes it doesn't,
depending on the characteristics of the particular
Ge diode and on component layout.

Adding a 1+meg resistor or a second Ge diode to ground,
to compensate for insufficient back-resistance of the detector,
has revived some builds, but at the cost of reduced sensitivity.

Because of its sensitivity and simplicity, it is definitely
worth experimenting with, but probably not ideal for beginners.

Hi Mike,

Its quite a while since in sold the set, (it was built in 2008), but it performed quite well after I built and ran it.
I can't recall just now what the total bands coverage was.

Best wishes

I don’t think it depends on diode back resistance either, altho this seems to be the most popular explanation.
I think it was about a year ago that i gave my own explanation here.
I need to remember in which radio’s schematic i saw this implemented with a vacuum tube diode.
When i paste that schematic up here, that should be the end of the ‘back resistance’ explanation.

No, it doesn't need a load resistor, The back resistance of the diode
itself is sufficient. That bothered me the first time I saw the circuit!

Does anyone have a working circuit for a Regen receiver using a tickler coil and using only bipolar transistors (NPN or PNP) and not any FETs like MFP102, etc.?

I have found lots of regens using tubes, or using FETs in the regen stage. I am looking for a circuit that uses just bipolar and also uses a tickler coil for feedback.

thanks

Hi

Because of loss of some finger dexterity in my left hand making
Fahnestock Clips
and small Alligator clips difficult I have gone to Bannana Jacks and screw
top Binding Posts.

My schtick is building Steampunk Radios/Sculptures.

Two tuned circuits Radios using Antique Tuning Components and Modern
Detectors and Audio Amplifiers. Open Breadboard, Variometers,
Variocouplers, Variable Condenser/Coil Assemblies, Vernier Dials.

Objects de Art'e as well as a functional Radio

Have you any experience, opinions and/or advice using FET's as passive
diode detectors?

In your Two Diode Circuit can one use two different types?

Also interested in Transistor Tube substitute circuits for use in complete
substitution of tubes in 1920's TRF Radios.

Joe,
Go to www.transistormuseum.com. Get the pdf file "History of Transistors Volume 1".
Go to page 23. It has a 2N35 NPN Transistor Regen Circuit. I built this when I was a kid. To make it work I added a resistor (100K or 1M) from the 9V+ to the NPN base. Used a High Impedance dynamic earphone.
If you talked into the earphone you had a "modulated osc" that broadcast to other radios.
It was neat. I took it to the barber shop that all us kids used and showed it off on the barbers radio that was next to all the comic books.
It could receive and send. It was one of those glory days.

2N35 NPN Transistor Regen Circuit

Rick

Thanks for the tip. However, the 2n35 is a germanium transistor. Even though I do have a few of these (from my uncle Lenny K2AQM, SK who worked at Bell Labs for 35 years), I still am looking for a circuit using silicon such as 2n3904. This type I have literally hundreds.

Any other ideas?

thanks

Joe W3TTT

How about the realistic globe patrol diagram. It uses a tickler coil and base winding and the regen transistor is silicon. A 2n3904 should work here.

I don't know if we are allowed to attach files, but I'll attempt it. If that doesn't work, I'll upload to a location and send a link.

I'm attaching two 2N3904 based regens. However, I'm partial to the one I created in 1994. It is what I call a "REFLEX REGEN" which makes the first transistor operate as a common base RF amp, then a common emitter audio amp! This is the perfect radio for someone too cheap to put three transistors in a box!

Thanks Jim! The schematics came through fine. Great ideas. And yes, I probably fall in the category of "too cheap to use three transistors". Actually, I have the FETs on order, but it is taking a long time to arrive, so I thought I would use BJTs like the 100 2n3904s that I have in my parts box. Also, the circuit would need to match the Tampax Tube Two circuit. I just built the TTT and it is a great circuit. Worked right from the start. Oscillates nicely. and most of all, needs no tuning variable capacitor (talk about cheap). The rig tunes nicely without a cap. I wanted to build some more of the same. Unfortunately, it requires a MPF102 FET transistor in the first position. And I was ALL OUT of these. So, I did order some more from an eBay Chinese supplier, and I am waiting for delivery. But I thought that I would seek out a circuit that is similar, using a tickler coil, and using bipolar transistor in the first position. But the only circuits that I could find used FETs or even Germanium transistors. For some unknown reason, nobody wanted to use a (cheap and plentiful) BJT. Oh, I did try, for a few hours at least, but so far, no cigar. I want to get it to oscillate, at least. I must be doing something wrong, because why couldn't a BJT oscillate using a tickler?

The TTT circuit is available here: www.afelino.net/tt2.htm http://www.afelino.net/tt2.htm

How would you adopt that circuit for a bipolar transistor?

I have found that the 2N3904 is a great little silicon device for RF service. As for JFETs, the 2N5486 is a good solid replacement for the MPF102 and readily available.

I'll look at the circuit later on today and try to comment. Anyway, that little reflex regen is novel and will surprise you!

Later.

I have a question: have you used the reflex circuit on SW, and if so, how does it work in the osc mode for CW, SSB reception?
Reason i ask is, i read in one of R. Penfold’s books on small receiver projects, that his reflex circuit was less than ideal for these modes, but there was no explanation.
I invite anyone to comment on this question.

Re the second circuit, i received a note from Ramon Vargas saying he has dropped out of the groups due to pressures of his work. He did send me a 3x 2N3904 regen
with a Vackar – style tuning circuit. Maybe i’ll scan it an post it here.

I don't know if we are allowed to attach files, but I'll attempt it. If that doesn't work, I'll upload to a location and send a link.

I'm attaching two 2N3904 based regens. However, I'm partial to the one I created in 1994. It is what I call a "REFLEX REGEN" which makes the first transistor operate as a common base RF amp, then a common emitter audio amp! This is the perfect radio for someone too cheap to put three transistors in a box!

27840. Floating diode circuit

Yahoo group: regenrx (2016 — 2017)
Date: 2017-03-30 20:13:29 UTC
From: Hubert Miller
Topic: 27840 Message: 27840

The output - load capacity is not large enough to charge to the audio peaks and hold the charge over audio cycles,
So the output can fluctuate above and below the averaged steady carrier output level. If this were a power circuit,
like a light bulb for the load, the series isolating capacitor would limit the DC output current, but this is a high
impedance circuit, so this capacitor has minimal effect. The circuit doesn't depend on diode leakage current.
I was the other night looking at a 1990s kit schematic for a "TAMAR Electronics AM radio kit". In this circuit the
diode is totally isolated by capacitors before and after it. Leakage thru the diode has nowhere to go, so it clearly
can't be diode leakage that makes it work. If there's a problem with getting the circuit to work, i suggest it has to
do with the values of the series and load capacitors. This is the same message i delivered a year or two back.

Hola amigos: The tuned circuit for the regenerative detector provides lots of room for experimenting... For example you may want a 10 turns coild on a one inch chunk of PVC pipe, and provides taps at 5 and 3 turns...giving the opportunity of experimenting with the feedback tap... use 5, or use 3...

Also using a ferrite rod from a defunct AM Band transistor radio will make possible listening to the top end of that band, from around 1300 kiloHertz up and reaching well into the 160 meters amateur band, that is still providing good signals , but that soon will be quite a challenge when the summer thunderstorms season begins...

2N3904 's and 2N2222's work well .... also tested 2SC371/372, but the 2SC373 showed what too much gain will do... i.e. make the regeneration control very critical to set properly

27848. Is the number of tuns including all the coil or just some of it?

Yahoo group: regenrx (2016 — 2017)
Date: 2017-03-31 07:22:30 UTC
From: Rob
Topic: 27841 Message: 27848

Along the lines of calculating the inductance then winding the coil and measuring with a meter......

this circuit calls for 8 turns then tap then another 4 turns of wire.

IS THE 8 TURN PORTION mated with the 250pF variable capacitor the tank LC to calculate?
OR
does the 4 turns after the tap get included in the inductance?

Noting the picture shows white wire 8 turns..then the tap ..then 4 turns of black wire.

.....so for a 100pF capacitor.... for 7Mhz......
25,330.3/(7*7*100)=5.17 microHenries

so does that mean the WHITE turns should be 5.17 microHenries
or all ..WHITE and BLACK turns should be 5.17 microHenries
??

FET regens are fun, but the need to run a source resistor severely limits how much audio you get out of the stage. Running tons of audio gain to make up for the loss can get squirrely. If you desire a regen for SSB and CW, you can achieve enough audio out of two transistors to drive a speaker to usable levels. Or run the detector straight into an LM380 for even better speaker performance.

It is all about getting rid of the r/c in the source and grounding it directly. Feed the gate a negative voltage through the "gate leak resistor". Couple the tank to the gate with only 2pf or so and you will see huge improvements in audio and SSB will start to have the clarity of a direct conversion receiver.

This technique will not do so well with AM, but for a SSB/CW rig it brings a regen receiver into a whole new world that can actually be suitable for a main receiver.

RCA RCA Victor Co.: Radiola III A AR-802 Type RL [Radio] ID = 618552 873x700
For model Radiola III A (3A, IIIA) AR-802 Type RL, RCA (RCA Victor Co. Inc.); New York (NY)
Country: United States of America (USA)
Manufacturer/Brand: RCA (RCA Victor Co. Inc.); New York (NY) alternative name RCA Victor Talking Machine

Year: 1924 perfect model Category: Broadcast Receiver or past WW2 Tuner
Valves / Tubes 4: WD11 WD11 WD11 WD11
Reception principle TRF with reaction (regenerative); 2 AF stage(s)
Tuned circuits 1 AM circuit(s)
Wave bands Broadcast only (MW).
Power type and voltage Dry Batteries
Loudspeaker For headphones or amp.
From Radiomuseum.org
Model: Radiola III A AR-802 Type RL - RCA RCA Victor Co. Inc.; New
Material Wooden case, TUBES VISIBLE.
Shape: Tablemodel, with any shape - general.
Dimensions (WHD) 300 x 150 x 170 mm / 11.8 x 5.9 x 6.7 inch
Notes
Battery setup: "A" battery for filament heating: Four or six 1.5 volt dry
cells connected in parallel. Good batteries are recommended, having
approximate dimensions of 2.5 inches diameter by 6 inches high. A two volt
(one cell, lead type) storage battery may be used if desired.
"B" battery for supplying power to the plate circuits, consisting either of
four 22.5 volt blocks connected in series. Two 45 volt plate batteries
instead of four 22.5 volt blocks may be used if desired.
For "C" one 4.5 volt Negative Grid Bias Battery.
Push-pull output. The WD11 were often replaced by UX199, using adaptors. 60
mA from 3 V made only 0.18 W per UX199, while the WD11 drew 0.25 A from a
1.5 V battery = 0.375 W, practically twice as much. The price was the same:
6.50$.
Price in first year of sale $65.00

27851. RCA AR-8501 1937

Yahoo group: regenrx (2016 — 2017)
Date: 2017-04-01 03:38:07 UTC
From: Hubert Miller
Topic: 27851 Message: 27851

I just received a manual copy i bought from 'Vintage Manuals' for my RCA AR-8501, 1937 4-tube ships regen.
It did kind of surprise me that RCA wasn't thinking more along the lines of superhets in 1937, but i suppose
the circuit worked, and it would be easier for the radioman to repair at sea, if he or she had to. The receiver
uses 2.5 volt tubes in a very conventional circuit, tickler coil with variable cap regen control. Coils are only
provided for 3 bands, 5-18 MHz. There is no audio control, only a gain control in the RF amp. Kind of strange
that it didn't cover any lower bands, like the 2-3 MHz marine band or the 500 kHz range.
-H

Topic: 27851 Message: 27852

Hello Hue,

You wrote about your surprise about RCA using the TRF regen late into the 30's.
I see a parallel situation with SOE and the Paraset in WWII.

In the case of the Paraset I decided two things. First, the designer placed great value on the idea of DIY repair. Very important when you can't take the set to the local (now vanished) radio repair shop. The key element in the design was local knowledge.

Second: We look back with the advantage of seeing the broad sweep of history. After WWII the SW bands were packed with stations - but what about 1937, 38, 39 ....? (I don't know, I wasn't there.) But that's my guess. So the lower selectivity of the TRF wouldn't be such a problem.

Then there's the problem (and cost) of two (or 3 gang) tuning caps.

Another interesting (resistance) radio set is the Polish Peepshtok. (or Pipschtok). This design is a 2 tube regen superhet - 6K8 frequency changer followed by 6K7 (or 6SK7) detector. When ARRL published a 2 tube design (in the 1941 handbook) it used a triode detector, followed by a triode AF stage to design the 'phones.

Looking at the Pipschtok again, it has a conventional regen control - pot in the screen grid of a pentode. I wonder how the designer felt about the comparatively low "Z" load to the detector? Generally pentodes look for a much higher "Z" load. I guess the design used only 2 tubes (in the receiver) to conserve battery power. If you're running from battery power in the forest, every mA of filament current is a drain on battery life.

But now I'm "off" your topic - the 4 tube RCA ship's radio.

I think your items are all "on-topic".
I read Pat Hawker, who operated a home station communicating with agent "outstations", saying that in WW2 the HF bands sounded like "contest night" on the hambands in later years.
Contrast that with pre-war or post-war. In wartime you had a large part of the male population working outside the normal economy, and radio was the main means of communications
for all levels of communications. So you had large bases, small bases, weather observers, weather observation planes, and so many others, making use of the frequencies.
However you are right about the marine bands pre and post-war. They would be busy, but disciplined, so a regen could function well in that environment.
The AR-8501 does have an RF stage and a two-gang tuning cap. I would hazard a rash statement and venture that all U.S. commercial product, communications-grade regens did not
have separate RF and detector tuning knobs (separate tuning capacitors.)

I noticed the schematics for the AR-8501 have in the name block (design, approval, etc.) the date 1934. The manual is dated 1936 and 1937, so maybe the manual was improved or updated.
Like some of the early manuals, there are items that seem offhand or unprofessional. For instance the tuning charts have hand-written (in the original) captions, not typed captions.

I noticed the grid resistor for the type 58 detector is 5M ohm. That's higher than most circuits work with.
When i looked at the schematic and saw that the output tube type 56 was the only one different, i thought, they could have wired a 58 as a triode, then the receiver would have used four
type 58 only, and that would have simplified repair parts stock.

As far as input impedance, i don't think the difference in a grid leak biased detector, the difference between a pentode and triode will be

Subject: [regenrx] Re: RCA AR-8501 1937

Hello Hue,

You wrote about your surprise about RCA using the TRF regen late into the 30's.
I see a parallel situation with SOE and the Paraset in WWII.

In the case of the Paraset I decided two things. First, the designer placed great value on the idea of DIY repair. Very important when you can't take the set to the local (now vanished) radio repair shop. The key element in the design was local knowledge.

Second: We look back with the advantage of seeing the broad sweep of history. After WWII the SW bands were packed with stations - but what about 1937, 38, 39 ....? (I don't know, I wasn't there.) But that's my guess. So the lower selectivity of the TRF wouldn't be

such a problem.

Then there's the problem (and cost) of two (or 3 gang) tuning caps.

Another interesting (resistance) radio set is the Polish Peepshtok. (or Pipschtok). This design is a 2 tube regen superhet - 6K8 frequency changer followed by 6K7 (or 6SK7) detector. When ARRL published a 2 tube design (in the 1941 handbook) it used a triode detector, followed by a triode AF stage to design the 'phones.

(To continue an email prematurely sent thanks to notorious Toshiba track pad quirks.)

As far as input impedance, i don't think the difference in a grid leak biased detector, the difference between a pentode and triode, at these frequencies, will be large enough to amount to anything you have to take into consideration.

Thanks for the reply. I will try that on my next regen. Perhaps if I use a diode in the source it will provide the negative bias. depending on the fet I may need 2 diodes. So far the radio is performing well. I added a fixed capacitance across the coil and added a 60 pf capacitor in series with the tuning cap. This narrowed the tuning range. It now tunes from 6.8 mhz to 8.2 mhz. Now the 40 meter band occupies a large slice of the dial. Yesterday I heard a station from Spain on ssb.

Hello Hue,

I read the description (by Pat Hawker) of SW band conditions in WWII. Fascinating.

The idea that the bands were packed with signals makes me even more interested in the use of the Paraset for "agents" in France. Looking at a map - I figure the sets were operating over a distance of 600 to 1000km (or 1500km to Poland). For a two 'tube' set working in a crowded band - (considering the consequences of failed communication) - they either had very skilled operators or good sets. Or both.

But the Poles used a different set - at least early in the war they used this "thing" called the "A" series (also known as the Pipzstok). As I wrote before: 6K8 converter, 6SJ7 or 6J7 detector and 6L6 MOPA. I have only seen this set mentioned a few times. I would be delighted to see a circuit. (Anyone??) One day I will build a set of comparable functionality. Not a copy - just a regen. superhet with the detector at 1700kHz. 12K8 + 12SL7 (not 12SN7. The 12SN7 is rather like the 12AU7. The 12SL7 is rather like the 12AT7.) Plus (god forgive me) - a solid state AF back end. (Will you forgive me, Hue? Yes? Yes? I hope so.) I hope to build this on a strong chassis with good quality capacitor. (I have one from a BC-221. I hope you approve, Hue!)

On the topic of difference in operating impedance. The detector (in the Polish set) was a 6SJ7, and it fed headphones directly. My point wasn't the input "Z". My point was the best plate load for the pentode detector. Pentodes always demand a higher "Z" than triodes, and in this case the headphones (maybe 4k or 8k ohms) were in the plate circuit of the 6SJ7. I would think a 50 or 100k load would suit the pentode better.

I have never measured the inductance of high "Z" headphones, but if their inductance was 1 Henry then that represents 6k ohms at 1000Hz. (Has anyone measured the inductance?)

To go in a slightly different direction: I read that the 6V6 makes a very functional regen detector. And I note that THIS beam tetrode drives a (comparatively) low "Z" load. Say 5 to 10k ohms. It would be very interesting to see a 2 tube regen superhet using a 12K8 and 12V6. (or 12K8 and 12A6. Metal - of course!) I would like to compare two different sets - one using a 12SJ7 detector and the other using a 12A6.

Remember - if you have the circuit for a Pipzstok - write to me!

FWIIW category -- I was born in 1938, and vividly remember hearing my father listen to SW on a nice Scott receiver.

As to tubes, I believe the first AC sets -- think stuff like Philco "Cathedral" set -- used the 2.5 volt heaters. Those were in general use through the 1930s until the octal 6.3 volt tubes came into use just prior to WW2. There were a few things like the 6E5 and 6U5 "magic eye" tubes that used the old 6 pin configurations. #80 rectifier as well. The #80 was a 5 volt heater.

As to batteries, etc., my Hallicrafters S20R, pre-ww2, I believe, use a #80 4 pin rectifier. There was an octal jumper plug on the back that could be removed so that batteries could be fitted. The radio was broad as the proverbial barn door, so I fitted it with a Heathkit "Q" multiplier. Also there were provisions for an S meter -- just the AGC line, so there was room in the Q multiplier for a dual triode (12AU7, or the like), balancing pot, and a small meter. Served me well for many years until I got some ARC-5 receivers and a BC-348.

I do not recall any commercial regenerative receivers in that era, though I built quite a few on them from "Radio for the Millions."

It is my impression that using existing technology and production facilities was paramount to the war effort. My dad was born in 1898, so was ultimately elegible for the draft, but was not called up. Thank my dad for brass plated door knobs -- DuPont unit he was with developed the brass plating technique -- we were short of copper alloys for ammunition in that era, and there was a push to develop a brass plating technique for steel. I remember playing with .50 cal. machine gun shell casings that were used in the experiments.

Most up scale console radios of that era had a SW band or two, in addition to the usual MW band. Remember listening the BBC before going to church in the mornings. We has a mast on our garage and a long wire SWL antenna fitted to it. I hooked up a Model T spark coil to it and took out every radio for blocks around...

That's my story, and I'm sticking to it..

Okay, Les, output impedance concern makes more sense and i understand what you were talking about. Yes, a pentode detector to a headphone almost seems to me like a mistake, but it was done,
and plenty of the published magazine projects did the same thing, altho as many others wired the pentode as a triode. The highest impedance magnetic headphones i have seen were around 12,000
ohm.
I had never heard of the Pip radio before. The only Polish sets i am familiar with were something like the AR-11 and AP-2 (my type numbers may be wrong) which were more advanced sets and
equal to anything produced anywhere else. I used to have a British radio magazine from the 1950s that had an ad for these Polish agent radios as war-surplus bargains. Now they all fetch $$$$$
prices. Didn't the British set use a combination superhet - regen detector also?
If you want to read a first-hand account of the resistance in Poland actually using such sets while trying to elude the Gestapo, there's a book titled "Fighting Warsaw" you can look up. It does not
give any description of the radios they were using, but the accounts are gripping and scary.
Just as a sidenote, it looks to me that in the Pacific area, no straight regenerative receivers were used by resistance groups. Maybe that was because due to it being not a question of hiding out
in cities, so the radios being of small size was not such a concern. Also it occurs to me, maybe the operators could not be counted on to be as well trained. Also a different communications system
was used, where small stations of just a few watts reported to a central station of higher power, which collected information and sent it on to Australia. (book reference, and also recommended:
"You're No Good To Me Dead".)
I do have a agent set from Europe, with a 3 tube regen receiver, and do want to put it on the air, but that still has to wait on other priorities. I was thinking that as there's a ham radio on-air event
called "Straight Key Night", maybe there could also be one called "Spy Key Night".
Also as a sidenote, there was a U.S. Navy radio of WW2 years that used a 3-tube regen, all 3S4 tubes, radio type CMS. No one really knows what it was intended for; no documentation or accounts
survive. My guess was that it was intended for the Philippine resistance but was rejected by the Navy in favor of other radios. This radio i think uses a 3S4 in the output but wired as a triode.
If you google "CMS radio" you can find some articles and photos.

A green LED gets you very close to the proper bias. It will work good, although you lose some strong signal handling capability. There is something about taking the source directly to ground and feeding the FET a stiff bias that makes it handle strong signals the best.

Hi all,

I was looking to build a simple and cheap CW transceiver and I've noticed that the receiver part is usually either a direct conversion or a rudimentary superhet.

This makes me wonder if it technically possible, or even desirable, to use a regency to receive and a simple unmodulated carrier to transmit.

Or maybe I'm not making sense at all.

What's your view on the topic?

Thanks

Thanks Paul. I'll check on that.

I'm also interested in the theory behind matching transmitters and
receivers (maybe we're going off topic here).

For example the regenerative receiver will have its tuning section. How do
you match that with a transmitter?

Plus the regen (just like a direct conversion, if I'm not wrong) will have
to be tuned to one of the cw sidebands to receive correctly. Therefore
there will be an offset with the transmitter.

How do I handle that?

In other words, assume I have a regen that covers, say, the 40m portion of
CW and likewise a transmitter covering the same band, how can I make sure
that:

a) they use the same antenna but not at the same time, and

b) they are synchronised so that the transmit frequency is the same as the
nominal receiving frequency (not the sideband).

If this is too off topic, please feel free to point me to other resources.

Thanks

Ottavio

Form is a 1 inch pill bottle.
Wire is 28 Gauge.
Taps are every 4 turns.
It was just for experimental purposes.
I played with it a little and heard Radio Havana Cuba last night.
My meter showed 2 to 43 microhenries.
With 25 microhenries near the middle of the coil.

I was hoping to get a vast array of band selection but I did not.
I was able to receive Radio Havana Cuba with the taps at both ends
and also when I tapped at shorter coil counts... 4 8 12 16 24
and combinations to shorten the two sides of the coil.

This is the last regen/transceiver I built. No 3 for here. I used hartley circuit for both TX and RX and kept them as identical as possible. Both are slug tuned as well. They are tuned by one control a dal gang variable cap BUT I removed on plate from the Rx side and added a small variable with approx the same value plus a wee bit to the rx side n parallel. As we know often our intended victim is not exactly on freq anyway so we need to be able to QSY the Rx without bothering the TX. By setting the slugs on freq with the small bands pread rx cap in the middle I can go above and below my Tx signal looking for my contact or correcting minor tracking errors.
The main tube is a double triode. I can never remember the number (ECL 832?) It is a dissimilar dual triode sort of like one half 12au7 (tx side) and one half 12ax7(RX side) giving good power on Tx but good sensitivity and reaction on RX. I added the 6aq5 Audio amp but really dont use a speaker on it so could have saved the effort.. It works pretty good and I enjoy having it on Air. Tis my own design but it was inspired by the Weskit BN-1. Although any relation is similar.

There is a lot of information about the ww2 Paraset
https://www.google.com/search?q=paraset&source=lnms&tbm=isch
https://www.google.com/search?q=paraset&source=lnms&tbm=isch

Peter vk3ye has built this one. Intersting also, because it is a solid state design:
https://www.youtube.com/watch?v=GJBRIf5Xkzw https://www.youtube.com/watch?v=GJBRIf5Xkzw
Inproved version with 30 watts:
https://www.youtube.com/watch?v=-WPAsaS5eFo https://www.youtube.com/watch?v=-WPAsaS5eFo

My 2 band Trx. The oscillator runs on 80m, for 40m the frequency is doubled:
http://www.dl0hbs.de/qrp-mas16.php https://www.youtube.com/watch?v=-WPAsaS5eFo

To hit the right frequency:
1. Zero beat the receiver to the other station.
2. Zero beat your transmitter to your receiver. In order to do this, the transmitter has to be isolated well from your regen receiver, otherwise the overloaded receiver is locking into the transmitter's frequency. In my case, only the oscillator is started without the power amplifier by pressing the zero button.
3. Last thing is, to turn the receiver either a little bit up or down, to hear the other station on a comfortable tone. Beeing able, to tune the receiver independently, is an advantage.

Best regards,
Bernd DF3DL

Dear OM

Yes. but I find with my regen transceiver there is a practical limitation if you answer someone with a modern superhet. I find difficulty spotting my transmitter to what I hear in the regen. while a regen is fun for listening, a dc or superhet is more practical for a transceiver.

There are 2 solid state regen transceiver kits now. The paraset 80 or 40m rig from qrpguys even has QSK, I have one of these. the bayou jumper lacks qsk tr switching. an observation, the WBR receiver I built seems more selective but no data yet.

OH U put Ur finger thru the paper there A good regen will out hear any modern superhet and I do mean any. If your tx is set up in synch with Ur Rx section they will track the same as in the one I pictured however my other transceiver also does. However I dont think anyone understands yes this works and works well.

This makes me wonder if it technically possible, or even desirable, to use a regency ...

Regency was the brand name of a nice superhet tube based shortwave receiver in the 1960's, marketed by Radio Shack of blessed memory. I remember sitting with mine in 7th and 8th grade for hours. Good memories! Thanks for the reminder.

Can anyone enlighten me as to how to wire this simple LDR module?
http://www.learnmorsecode.com/pic/LDRmodule.jpg
http://www.ebay.com/itm/200982532672

I thought it was supposed to be wired to PLUS and MINUS volts on VCC GND
and then the output SIG would show voltage when exposed to light.

But I get no SIG change when I illuminate it.

I can't find any documentation on it.

Hi,

In the first few seconds I wondered why you wanted to use a Regency in a transceiver but quickly realized it was a typo. Context cane be our friend. I was once again pleased that I set my autocorrect to autosuggest. I *always* have the final say so I make my own mistakes <evil grin>. More recently Regency made solid state V/UHF "police" scanners - also worked on the ham bands.

As you have seen, there are hams who use regen</cy> receiver section in their transceivers. In my experience the statements about regens "outhearing" *any* other receiver are true.

Good luck with your project.

Hi Rob, do you have The board schematic? I tried downloading it from the eBay page but couldn't see anything. Looks like it's just an LDR feeding a op amp used as a comparator. Not sure at what light level the switch point is supposed to be, so It might need to be really really dark to see a change? For some peculiar reason the eBay specification lists resistance change and I bet that is of the LDR part itself. I suspect the board output is a voltage change. Try measuring the voltage on both leads of the LDR, Referenced to ground. You should see one of them changing as the light level varies. Good luck,

Hello Ottavio,

I think you'll find a number of list members use a regen receiver "on the air". Don springs instantly to mind and (of course) our "Amigo" Arnie. Tony Langton, GM4HTU, built a solid state Jones superhet. He said, "Results are impressive. There is only a slight warm-up drift and SSB is easily copied."

I can agree with Tony - using his solid state design (not exactly his design, but similar) I easily copy SSB (here in Australia the bands are NOT crowded). On 80m I can easily hear stations 1200km to the south and north. The secret is in the design of the tuning mechanism - not the electronics!

Don uses a 'straight' regen. He likes simplicity. However, if I wanted to build a regen set to use 'on air' (and I do) I would build a 3 tube Jones Superhet. Some (Arnie and Gary Johansson) prefer a design called Regenerodyne. I'm for the more conventional Jones superhet.

Can I suggest you sort out your transmitter, power supply and transmit-receive logic before you build the receiver? If you want a circuit for T-R logic, I have one. (But solid state. It won't switch the B+ supply (hundreds of volts) unless you use a relay.)

Finally, can a regen set give reliable communication? During WWII the poles used a set called Pipzstok for comms between "London" and Warsaw. The receiver? 6K8 and 6SJ7 detector. 1200km Crowded bands. And the transmitter? A single 12L6 - sometimes run in an oil bath to keep it cool. Today I would use a minimum of 3 tubes in the receiver. Tubes are cheap, and every extra tube gives a lot of extra performance. I would use a separate detector (rather than an oscillating detector).

Build your set solidly. Most builders take the attitude "Oh, I'm just building a 2 tube regen set." They skimp on the tuning capacitor and dial. They don't brace the chassis (etc). Build your set like a battleship - that's the secret of a good set to use "on air".

I hope this helps.

Les

Dear amigos : I am really happy that the relevant topic of the mechanical construction of regenerative , Jones superheterodynes and my Regenerodyne optimized design has been brought to the attention of the regenX list members.

ZL2JJ is my mechanical reference for a home built regenerative... including the need for extensive shielding, good grounding to the chassis, and good voltage regulation.

From a mechanical point of view the ideal air spaced variable capacitor and dial mechanism is to use one from a BC221 or LM heterodyne frequency meter, or from the Soviet clone under the name of CHA4-1.... Second choice will be the air spaced capacitor and dial mechanism from any of the Command Set receivers like BC454 or BC455, or if you want to listen to lower frequencies use a BC453 assembly.

Take also into consideration the use of well filtered and regulated direct current for the vacuum tube filaments, as well as for the plate and screen voltages...

Even the simplest regenerative like the Kitchin design using just three NPN common transistors can provide excellent performance if you make a big effort in assuring excellent mechanical stability, and use the best possible voltage regulation, plus high quality regeneration control potentiometer...

Hi,

Building radios like battleships is really required for good performance from superhets too. Little toy radios that flex and bend will drive you to drink or maybe just to a stamp collecting hobby.

27890. A DIFFERENT RF filter for the Desert Ratt 2

Yahoo group: regenrx (2016 — 2017)
Date: 2017-04-07 20:57:28 UTC
From: michaelleblanc1@...
Topic: 27890 Message: 27890
Attachments: 1 described; binary payloads are missing from this source WARC

I've finished my second build of the Desert Ratt 2. It's fairly stock, with a couple of very minor changes. Performance is stellar, with one exception: I'm occasionally getting breakthrough of local FM stations.
As you know, the DR2 comes equipped with a high-pass filter to block local MW stations. I'm on the east coast of Canada, and here we've closed the MW stations in favour of FM stations, so I don't need the filter. I tried removing the filter, but the radio went quiet, I presume because of an impedance mismatch. Has anyone had any experience with substituting the simple high-pass filter for a low-pass filter that might knock back some of the FM boomers around here?

I tried replacing a Butterworth 3-element Pi filter using the online calculator at http://www.calculatoredge.com/electronics/bw%20pi%20low%20pass.htm http://www.calculatoredge.com/electronics/bw%20pi%20low%20pass.htm, using 1750 ohms as the impedance and a cutoff frequency of 9.15 MHz -- these values were selected to fit my available components.

However, the filter dropped the available RF energy from the antenna to almost nothing; again I'm presuming that 1750 ohms is either too much or too little impedance.

Anybody have experience with this type of problem?

It's not as neat as a direct conversion arrangement (with a shared local oscillator offset on tx) but it can be done if you've got a good stable regen.

A difficulty is netting them onto the tx frequency as the strong signal from a tx oscillator can overload them (especially if the regen is finely set).

This video is a regen rx/tx combination. It's worked Canada from Australia.

https://www.youtube.com/watch?v=-WPAsaS5eFo https://www.youtube.com/watch?v=-WPAsaS5eFo

This is the earlier version of that receiver

Thanks Peter,

It was actually your video about zero beating on direct conversion
receivers that prompted my question. Up to that point i thought you could
only connect a trasmitter to a superhet or a direct conversion.

Interesting link for galena.
BUT
I couldn't figure out how to buy at retail level.
Anybody out there figure this
out?::

1 inch chunk of galena for $10

http://www.ebay.com/itm/222251636625

Probably enough galena to may 1,000 diodes.

or 100 chunks to play with cat whiskers.

I ordered some of this galena.

Is there any particular rules when selecting the type of wire
to make the point contact cat whisker?

I have copper wire , steel wire, silver wire..... steel spring wire.....

Hola amigos ! My first galena detector receiver had a cat's whisker wire made of what seemed to be spring steel. It was mounted on a very flexible arrangement that had a ball and socket support... You could let loose the clamp sorrounding the ball that supported the cat's whisker until you found the ¨sweet spot ¨ , then one had to tighten the clamp to keep the radio working at maximum efficiency that was achieved at the sweet spot on the galena stone fragment.

By the way,,, that radio used a coil wound of common enamel insulated wire that was sanded at the half of the turn so that a wiper could move over it, selecting how many turns you wanted and thus tuning to a station... My radio had a single mica capacitor in parallel with the coil...

I made several clones for my high school friends, and results depended a lot according to the location of the station or stations that could be picked up, the length of the antenna and the use of a ground system (typical ground was a wire connected with a C clamp to the cold water pipes..

Earphones were of two types, high impedance magnetic ones and ceramic also high impedance crystal single ear earphone.

Using the Russian D9E and similar super sensitive germanium diodes in a voltage doubler or voltage quadrupler detector circuit provides much higher volume than what can be obtained with the primitive galena crystal, or the GEM shaving blade...

Rob,

As you can divine from the good professor's reply, the spring steel is what you MUST use.

The tip of a 6-8 turn, generally conically not linearly wound spring steel wire, to a diameter of 1/8th inch at the end that aims at the galena, that from a diameter of about 3/8"that hitches to the hand-operated control arm and knob.

Basically, the small end of the spring steel has to feel around the surface of the galena to find the "honey spot" (that best known while you listen for maximum volume). Once located, press down with the hand-operated control on the catwhisker so that it will stay in that honey spot.

Possibly the internet will reveal pictures of catwhisker assemblies. To my knowledge, there was no firm tie-down facility to secure the catwhisker in its honey-spot location once that had been discovered.

72,

Charles

A popular choice with galena was phosphor-bronze wire. It's springy
enough without being too stiff. Other than a very light contact will
destroy the rectification, so there's a tradeoff between sensitivity and
mechanical stability. Hot spots on galena consequently don't stay hot
for long, but the need for continual hunting is part of the charm.

Despite lore, the chemical composition of the wire is not particularly
important for these types of detectors, as the rectifying barrier is
already on the surface (it's not a simple Schottky contact). Its
dimensions and mechanical properties will make a far bigger difference.

Tom – what is the objection to this: what if one used something like steel wool, pressed against the galena, to acquire a contact, or contacts? I was told once this does not work, but it’s not immediately clear to me, why not.

I have a nice piece of galena a friend sent me from Peru. It still needs mounting in, i think it is, “Wood’s metal”.

One idea for a demonstration ‘crystal radio’ is to use a 2 diode, fullwave voltage doubler. One diode is a fixed modern type and one is the old catwhisker style. Note, you must use very high
impedance piezo earphone with this circuit. Each diode output is across a 0.001 uF (1 nF) capacitor. Then, you can hear a broadcast even with the catwhisker not adjusted,
and you simply tune in a station, and then peak the catwhisker adjustment to bring up the audio louder. This is for a set that you want to demonstrate the old style diode detection.

Hi Hue,

If you can manage a single point contact (e.g., by having just one of the steel wool whiskers make contact with the crystal), I see no fundamental reason why steel wool wouldn't work. But if you just press the mass of the steel wool against the crystal, the probability that some portion of the wool will make an ohmic (rather than rectifying) contact is nearly 100%, and that's all it takes to short out the diode and make it not function. You really want to arrange for a single point of contact, and even then, you still need to hunt around for a good spot.

As for Wood's metal, that's definitely the classic mounting method for making a good ohmic contact to the crystal body. But if one is in a hurry, a good alligator clip connection to the lump of crystal often works as well.

Tom

Hi

The $64.00/$64,000 question!!
We are dealing with semi conductors, the "crystal" is the semi & the Cats Whisker is the conductor. Said Cats Whisker drawn to a fine point and sanded regularly to remove any oxide(s). In theory the most conductive wire that does not oxidize easily: however when push comes to shove any of the wires will do.
For interesting results wire a pair of Binding Posts in parallel to accept a range of of fixed Detectors the ubiquitous 1N34, an LED as an ersatz S Meter, Schotkky Diode, and MOSFET as a passive detector.
Also consider the other direction Foxhole detectors Razor Blades Coins and a pencil point as a Cats Whisker
Note that the Experimenters Kit contains a Schotkky Diode.

Thanks, Tom ! That explains why the steel wool multi contact idea does not work.
I think i read years ago that something like this was used for another semiconductor material, corborundum, but i don’t know why that approach would work there.
As to your suggestion to just use an alligator clip grip on the crystal, great ! That removes another hurdle.
-Hue

>Hi Hue,
If you can manage a single point contact (e.g., by having just one of the steel wool whiskers make contact with the crystal), I see no fundamental reason why steel wool wouldn't work. But if you just press the mass of the steel wool against the crystal, the probability that some portion of the wool will make an ohmic (rather than rectifying) contact is nearly 100%, and that's all it takes to short out the diode and make it not function. You really want to arrange for a single point of contact, and even then, you still need to hunt around for a good spot.
As for Wood's metal, that's definitely the classic mounting method for making a good ohmic contact to the crystal body. But if one is in a hurry, a good alligator clip connection to the lump of crystal often works as well.

Dear amigo Rob: To the best of my recollection (this evoked memory had to be brought back from 1955/1956 !!!) it was one of those ¨postage stamp mica capacitors ¨ with dots of different colors to indicate the actual capacity... But I can not remember the actual value...

Doing some ¨reverse historical engineering¨ capacity values between 100 picofarads and 500 picofarads could be tested wih a classic air wound coil on a three or four inches diameter PVC pipe... and you may also try a ferrite rod Broadcast Band antenna...

If you use a razor blade as the ‘semiconductor’, here’s an idea that enhances the ‘visual effect’.
Get an old pencil and keep it in the pencil sharpener until it’s so short that you have it almost ground down
to the eraser holding metal. Then carve off the wood and the eraser and expose a little of the central
graphite core. Wrap some wire around the protruding graphite. This is the other diode contact. The
pencil stub with the sharpened point end is adjusted onto the razor blade, and suspended in place or
held by a #12 gauge stiff wire attached tightly to it.

Rob and group. The go-to gang for crystal radios is

http://www.shopping-cart.midnightscience.net/

They got mounted galena, whiskers, and a wholebuncha related stuff and books.

Zinc oxide makes a good detector. See this website.

http://sparkbangbuzz.com/zinc-oxide-diode/zinc-oxide-diode.htm

Another good reference is at

http://www.crystalradio.net/minerals/index.shtml

The resistance of the catwhisker wire makes little difference, as the spreading resistance of the contact point itself will dominate. The geometry and mechanical properties of the wire matter much more.

And yes, a great many natural semiconductors work in place of galena. Pickard investigated over 30,000 combinations of wire and minerals, and patented a silicon detector in 1907 or thereabouts. Carborundum is unique in its tolerance of very high pressure contacts. The razor blade you mentioned works well, and has a lot of WWII history behind it. I discovered some years ago that baked pennies (and many copper coins from other countries) are also a reasonable semiconductor. Making successful point contacts is trickier than to galena, but a gentle touch with a 0.5mm mechanical pencil lead seems to do ok. One may also recycle integrated circuits: Gently abrade away the top surface of the chip and make a point contact to it (the "die paddle" provides a connection to the bulk). That produces a good detector with a much lower knee voltage than the 0.6V one expects from silicon. Finding a good spot is also much easier, thanks to the uniformity of the silicon used for chips.

Tom

27914. Re: [regenrx] Re: what type wire should a galena cat whisker be made out of? oxides of silver

Yahoo group: regenrx (2016 — 2017)
Date: 2017-04-09 06:56:39 UTC
From: Rob
Topic: 27678 Message: 27914

This is for historical purposes show and tell , for kids, so I will not be exploring anything
with razor blades.
I don't need some parent coming back at me because I sent their kid on a scavenger hunt for razor blades.

Ken...I am very familiar with all 3 webs sites..... but have not been there for a few years.

I have no problem getting parts.
1,000 transistors cost $10
100 D9B germanium diodes cost $14
I'm not looking to do any caveman or POW electronics here.
The task at hand was to merely demonstrate cat whisker galena "detection" as it was used
in the early days of radio.

food for thought.....

Pickard investigated over 30,000 combinations of wire and minerals, and patented a silicon detector in 1907 or thereabouts

“The oxides of silver are conductive”. So I would consider a thin silver wire.

By all means experiment with lots of ideas. Safety pins work well with carborundum, less well but serviceably with razor blades, and not too satisfactorily with galena.

27917. 2 to 5 pF antenna decouple capacitor

Yahoo group: regenrx (2016 — 2017)
Date: 2017-04-09 22:08:54 UTC
From: Rob
Topic: 27917 Message: 27917

The KITCHIN regen calls for a 2 to 5 pF capacitor to decouple the
antenna capacitance when using an
outdoor antenna instead of a simple short whip antenna:

http://www.learnmorsecode.com/regen/00regen.html

Does the choice of a 2 ,3 ,4 or 5 pF capacitor make any impact on the
circuit operation
to the point where one should be used instead of the other?

I'm not repeating Pickard's investigating 30,000 combinations of wire
and minerals for a patent.
I'm just mounting some galena in a pretty holder and making a cat
whisker ....probably with spring steel wire..... just because I have it
already.

From: Michael
Topic: 27917 Message: 27919

Rob,

Your floating-diode build is obviously working well with the
Russian germanium diodes. The design is very sensitive, so with
an external aerial, very small C1 capacitance is required.
Even a gimmick will suffice (a few twists of insulated wire).
Too much capacitance will overload the detector. Experimentation
will determine the optimal value of C1 with your antenna.

Keep us posted on your findings!

27921. Re: [regenrx] 2 to 5 pF antenna decouple capacitor

Yahoo group: regenrx (2016 — 2017)
Date: 2017-04-09 22:40:49 UTC
From: Prof. Arnaldo Coro Antich
Topic: 27917 Message: 27921

There is another possible approach for connecting an external antenna to
the Kitchin regenerative version with NPN transistors that works very well.

Prepare a double tuned top coupled bandpass input filter, using the
standard low impedance inductive coupling to the antenna...and couple to
the detector tank circuit with a very small variable insulated air
spaced capacitor.

You will notice immediately better reception of the short wave signals
because you are introducing FRONT END SELECTIVITY to your radio...

BTW... my Arnie Coro's PI network antenna tuner is also a good option
for the input from an external antenna to any radio or transceiver

73 and DX

Arnie Coro

Hi
I would suggest some type of passive Antenna Tuner and deleting said
Capacitor,
Radios are Tuned Circuits in Series the more the better.

I'm not looking to redesign the simple KITCHIN circuit.
I just want to know if 2 pF is and better or worse than 5pF when
choosing components.....
for this simple kid radio.

Rob,

With an external antenna, start with 1 or 2 pF (or a gimmick)
for C1 and increase it to 5pF if needed. The optimal capacitance
before overload will largely depend on the length and height
of the external antenna.

Topic: 27917 Message: 27929

I wondered about this before, Arnie, so thanks for your input. I wondered whether a two or even three tuned circuits, with no gain, in front of a regen detector would be a worthwhile circuit.
I suppose rather than the close-in selectivity, which the regeneration creates, extra tuned circuit or circuits would improve the regen ‘skirt selectivity’ for farther off in-band signals, which is where the regen falls down.
So do you think a tracking adjustment on the tuned circuit facing the antenna would be necessary, or is the overall bandpass effect great enough for the first tuned stage, with the second (or last) tuned circuit actually defining the working frequency?

I had reworked the artwork to spread out crowded components.....
the goal being make it easier for kids who never soldered before.

And
as soon as I plugged in the 9 volt battery I heard CW.
I WAS surprised that I heard CW.
I had not found ANY CW using the first KITCHIN regen.
BUT
it was NOT CW QSOs ... it was the beginning of

Dxers Unlimited radio hobby show ....Radio Havana Cuba

so I recorded some of it.... Arnie talking about the PARASET rig:
http://www.learnmorsecode.com/regen/02REGENarnie.mp3

BIG smiles here.

ALWAYS
I always share.
Go to
http://www.learnmorsecode.com/regen/00regen.html

Scroll down to the bottom of the page for the version TWO.

http://www.learnmorsecode.com/regen/02REGENkitchinPCBa9.jpg

NOTE THAT MY finished board has trimmer pots instead of outboard full
size pots.
I had to drill some extra holes and rearrange a 33uF cap but it all fit
fine.
I make copper traces 10 times fatter than really required so corrections
happen
without running out of copper.

27933. sharing PCB artwork

Yahoo group: regenrx (2016 — 2017)
Date: 2017-04-10 04:39:31 UTC
From: Rob
Topic: 27930 Message: 27933

I don't know if this works for everybody but I found that if I right
mouse click on an image and save it
to my hard drive and then open it with an image viewer .... I get the
right size printed on my laser printer...
BUT
if I have my web browser print it I get a smaller image which is no good
for PCB printing.

I use yellow toner transfer paper. I think it costs 15 cents....
and fits 8 70mm X 100mm PCB images.....
so ..... between the cost of the yellow paper and 45 cent copper clad
board it costs about
50 cents to print a PCB.

This particular project regen was able to get away with dirt cheap
components... trimmer pots instead of full size pots........ and could
easily be built for less than two dollars for the PCB and components on
the PCB.

7 cent electrolytics ... one 10uf... two 33uf = 21 cents
1 cent ceramic caps.................. qty 6.......... = 6 cents
3 cent resistors.......................... qty 6...........= 6 cents
3 cent 1N4148 diode.................. qty 3..........= 9 cents
30 cents 5K trimmer pot...........qty 1..........= 30 cents
22 cents 150 trimmer pot...........qty 1.........= 22 cents
1 cent 2N2222A transistor...........qty 3......... = 3 cents
10 cents germanium diode D9B qty 1....... = 10 cents

The only "expensive" part is the variable capacitor and they can be
bought for under $3.00.

Hi
From following the messages it seems that the circuit boards have been made in quantity.
Would any be available for me and my Senior Citizens SWL/Scanner Club.
We have a side project of building some Steampunk Radios with Vintage/Antique components, Variometers, Variocouplers, Variable Condenser/Coil Assemblies with modern semiconductors and circuits.
We use Breadboard techniques so we get an Object de Art with a highly functional radio.
Basically Crystal Radios and one or two active stages.
We also have a Radiola III & IIA with regenerative coils to use with circuit board.
We can use either the old or new board(s) How much for three to six Boards?
Thanx

27937. Re: [regenrx] 2 to 5 pF antenna decouple capacitor

Yahoo group: regenrx (2016 — 2017)
Date: 2017-04-13 00:18:11 UTC
From: kevin asato
Topic: 27917 Message: 27937

How about 2 pieces of insulated wire about 2 inches long. insulation can be plastic or enamel. doesn't really matter in the long run.Adjust the capacitance by the amount of twists in the wire; more twists == more capacitance. Also known as a gimmick capacitor. The 2" is random. It provides enough wire to grip while twisting. One or two twists should get you in the ball park of something 2 to 5pf, more or less. No need to be precise at it allows for coupling the antenna to the radio.

73,
kevin
kc6pob

Well. . . Try them and find out, the fun's in
the experimenting.

27938. D9B D9K D2D Russian diodes

Yahoo group: regenrx (2016 — 2017)
Date: 2017-04-13 04:29:37 UTC
From: Rob
Topic: 27938 Message: 27938

After success with the D9B diodes I poked around EBAY and found more 5 cent Russian germanium diodes.
Not really knowing what to expect I ordered D9K and D2D diodes, just to experiment.
They are labeled:
D9B USSR Germanium Detector Diode 10V 40ma 100 KHz
D9K USSR Germanium Detector Diode 30V 30ma 100 KHz
D2D USSR Germanium Detector Diode 50V 16ma 150 MHz
Any thoughts here?
I'm just looking at replacing the 1N34A diode in simple crystal radios and the KITCHIN simple regen.

27939. Re: [regenrx] D9B D9K D2D Russian diodes

Hola amigo the D2D and similar high frequencies capable diodes were used as video detectors in Soviet days TV set like Krim 206 , Rubin 205 and Elektron 205 black and white sets with 23 inches picture tubes.

Have you ever heard about the ¨ Voltage Quadrupler detector ¨ published in SPRAT the British QRP Club magazine ?

At the low price of 10 cents each, it would be interesting to experiment with that detector configuration and learn if it increases de audio output on the crystal set.

Ben Tonque of Blonder Tonque Laboratories published extensive experimental work with crystal radios, worth all the time reading those very well written highly technical papers.

I read one once , enjoyed it a lot, but could not download others that Ben also wrote. BTW, I understand that not too long ago he passed away. Never knew if he was an amateur radio operator .

Russian diodes type D9 are tested as rectifier by the manufacturer at two frequencies: 0.1 MHz and 40 MHz. The frequency 0,1MHz is used as reference. The ratio of rectified currents should be no less than 0.6.

27941. KITCHIN regen version 3

Yahoo group: regenrx (2016 — 2017)
Date: 2017-04-15 05:58:15 UTC
From: Rob
Topic: 27941 Message: 27941

KITCHIN regen version 3:

All parts spaced for newbies:

http://www.learnmorsecode.com/regen/03REGEN.jpg

The goal was to make a repeatable dirt cheap short wave receiver for scouts.

No real difference between versions 1,2 and 3.
Just stretched the parts spacing to be easier for newbies to solder.

All three versions heard Radio Havana Cuba.... 1,300 miles away from here.

http://www.learnmorsecode.com/regen/00regen.html

This looks really good, Rob!

Do you notice any difference in performance
between 1N34A and D9B germanium diodes - even
from the same batch?

27943. The new printed circuit for easier assembly of the 3 NPN transistors Kitchin regenerative

Yahoo group: regenrx (2016 — 2017)
Date: 2017-04-15 17:42:57 UTC
From: Prof. Arnaldo Coro Antich
Topic: 27943 Message: 27943

Dear amigo Rob:

A lot easier not only for kids, but also for old timers ... a very good idea to design a ¨wide spaced¨ circuit board.

Could you please send the side where the copper traces are ?

The photo of the upper side with the parts came in very nicely !!!

Has anyone tried to use an LM317 variable regulator instead of the 3 silicon diodes ?

Perhaps the radio can be further optimized by finding out the optimum voltage supplied to the NPN transistor.

It is quite clear that each diode will ¨regulate at around 700 millivolts, so three in series should provide about 2.1 volts to the circuit. The LM317 can regulate down to 1.3 or 1.4 volts, so it will also do around 2.0 volts... You can then experiment and find out if a somewhat higher or lower voltage will make any difference in the performance of the receiver...

And YES... I am aware that adding the LM317 to replace the 3 silicon diodes is not a good idea for a receiver project that aims at simplicity and low cost...

Hi

Speaking of "changes" I am planning on replacing the Tank Tuning Feedback components with Antique/Vintage components: (*L1)* Coils & Variometers that have Tickler Winding's and larger (*C2)* Tuning Capacitor to match the Antique Inductors.

Also noticed a typo error third paragraph "Rallows" R1 allows?

SHARE PICTURES and schematics if you change anything.

Rallows user control for regeneration..... is R2 150K pot.

I did not write the PDF so typos and all... the JPG is the same as when
it was first written.
....

Arnie...copper traces side:
http://www.learnmorsecode.com/regen/03batch1.jpg
http://www.learnmorsecode.com/regen/00regen.html

I did not do any performance experiments.
I simply created it per the instructions. My deviations were by advice
and parts on hand.
Like version 3 uses 1N4454 instead of 1N4148.

I see LM317 is readily available for 10 cents.... so cost really is not
an issue.....
so....
just out of curiosity can anyone modify the circuit ...take a picture
and show me how that gets wired.

If the performance is vastly improved then I would use it.

I can't tell any difference.
And I did swap out 6 D9B diodes to see if they all worked and all gave
the same good results.

That is very encouraging, Rob!

I must rebuild my original and try more germanium diodes.
I have an assortment of uncertain origin from scrap
tag-strips etc. The quality of the germanium diode
would seem to be the determinant factor, which must
be why Kitchin reported his success.

I am sure your scouts will learn a lot from your
perseverence. That is the essence of "amateur" radio.
Hopefully your endeavours will enthuse many future hams!

Its not a kit.
Its an experiment.
I'm looking for something to share with scouts... or anybody... any age....
that is dirt cheap to build using the cheapest parts.
I'm not selling kits.
But I will mail a PCB to you.

all I want in return is pictures of anything you build to share with
newbies.

Do you have the ability to drill the component holes?

Give me your mailing address.

27950. Adding an RF amplifier?

Yahoo group: regenrx (2016 — 2017)

From: rhulett1@...
Topic: 27950 Message: 27950

I am looking for a circuit to isolate the antenna from the detector in my 2 tube regen from Aug 1951, similar to the National SW-3. Mine uses a 12SJ7/12SL7. Does anyone have suggestions for adding RF amplification? Maybe someone has already built something like this. Any circuit advice for this? I hope to use the existing chassis as a basis for 3 tube.

Hi maybe you can find space for an additional tube - 6C4 - and the additional coil/per band. You can rewire the 12 volt tube for 6 volts on the heaters. You will also need a dual ganged tuning cap (two identical sections) and it may need additional space. Those things can all be accommodated in a new build but might be more difficult if you are modifying an existing radio. I would like to revisit the 6SN7 regen from the old handbooks and build it with the rf amp. I have an SW-3 here and it is a pleasure to use. So you can see that I have less motivation to build the receiver you are talking about.

Good luck with your project. Please keep us posted.

Hello,

I have a good condition National SW-3, with 20 meter coils only and am looking for a reputable restoration technician to go through it for me. Age/heaing/eye-sight are catching up with me so I will not attempt to do it myself.

If anyone could recommend someone to me to do this, I would appreciate any input/experiences you have had with the person you may recommend.

Any input would be appreciated - along with a source for a 40 meter coil and an 80 meter coil.

Curt,

On the PARASET, the top of the detector's link coil goes through a
series 100pf capacitor to the SPDT switch which connects the antenna to
either the receiver link or to the transmitter. So will

This work for yo? It also has no rf amp.

Dear amigo....

A very easy to put in practice circuit to isolate the antenna from the regenerative detector stage is a simple grounded grid triode amplifier stage...

Any triode or triode connected tube will do the job !
My prototype regenerative that has proven to be very effective uses a 6AK5 pentode with the screen grid connected to the plate and the control grid connected directly to ground.

The cathode acts as the signal input electrode...I use a little trick to connect a 1000 ohms carbon potentiometer so that it will act as a cathode resistor for the grounded grid stage, and at the same time it is used as a primitive yet effective RF signal attenuator... Connect the good quality carbon track potentiometer (you can also use a wirewound potentiometer of good quality , because the inductance of the high resistance per unit length wire is negligible at short wave frequencies) Connect the bottom of the potentiometer to ground, the top goes to the cathode of the triode tube and the center connection goes to a small capacitor to the antenna... The capacitance of that capacitor leaves a lot of room for experimenting !!! The plate circuit of my grounded grid amplifier stage uses a standard carbon resistor of around 100,000 ohms or an RF choke of 1 mHy or 2.5 mHy... again lots of room for experimenting. From the plate of the triode I connect a capacitor to the top of the regenerative detector tuned circuit..., and you can try connecting it from the ground end up at a few turns .... experiment for best results... BTW... this radio uses a very simple power supply that provides 36 volts regulated to the 6AK5 regenerative detector plate and to the screen grid potentiometer that controls regeneration... The grounded grid RF stage is fed from the 120 volts DC unregulated supply that also provides plate voltage for the triode of the 6BM8 or ECL82 , and for the plate of the output tetrode of that tube... Audio quality is excellent, and I am now building yet another one to be used at our amateur radio club training program... Good results for ham radio reception of CW and SSB signals has to do with the quality of the air spaced tuning capacitor and the type of dial used for proper slow motion tuning.... The ideal capacitor and dial mechanism , without any doubt, can be found at the bay place looking for a BC221, LM or the Russian CHA4'1 heterodyne frequency meters....

My advice is that you first try to build a prototype to familiarize with the regenerative circuit using the Hartley circuit and screen grid control of regeneration... and then when you are happy with the results, build a ¨ final version ¨ .

Arnie, your expert advice is always highly appreciated,
especially by those of us with limited resources.

Where possible, an added schematic would often be a great help
for implementation and expermentation.

Do you have a website with schematics and descriptions?

¡Saludos!

Dear amigo Michael and all participants of our e'mail distribution list...

Thanks for the nice comments... It is not expert advice.. let's call it
the recommendations that come from may years of ¨cacharreo¨, the word in
Cuban Spanish that is equivalent, more or less with ¨tinkering" in English.

Sorry to say that I am a very poor user of graphics software programs...
so following requests of many of my Dxers Unlimited radio show program,
the ¨solution¨ that we found was to write a very comprehensive ,
detailed, step by step explanation of a circuit, something we
¨discovered here in Cuba to pass along radio circuits to radio amateurs
that live out in the countryside...

This is an example of how we did it---

¨You draw a seven pins miniature socket, and number the pins from one to
seven... This is for a 6AK5 tube type.... Connect pin 3 to ground, and
pin 4 to the 6.3 volts AC voltage. Solder a .01 disc ceramic capacitor
from pin 4 to pin3....

I had a terrible time with graphics software.
The tools and fonts are way too small for my eyes.

So I take a low tech approach.....
I print out the schematic and draw black dots where components would
attach to
a circuit board:

http://www.learnmorsecode.com/regen/00REGENkitchenbig.jpg

then I connect the dots with a heavy marker.....

THEN I take a picture of it and there isn't much more high tech stuff to do
with it that standard cell phone camera or paint programs can't do easily.

Eons ago I used something called a resist pen to draw lands on circuit board copper. Then etched with Ferric Chloride. With a resist pen (if they still exist), wouldn't need to go through the transfer process. Just draw it on the copper and etch it.

I found them at first site checked for between $6 to $9. Guess will buy one and try out that process with the peroxide/muriatic acid etch.

My primitive, yet very effective way of making printed circuit boards uses carefully cut lengths of PVC electrician's tape... I can also make ¨ islands¨ that like the lines are cut with a razor sharp blade.

My ¨chemical¨ for processing the boards is made using hydrocloric acid to which a load of rusty nails is added... after some time the resultant liquid will etch the copper left on places where the PVC electricians tape is not present...

Unetched virgin boards are not easy to find locally, so we many times look for old boards... clean them and remove all the copper and then make the circuits wiring by linking parts in holes drilled with a dentist's tool...

and all I can say is that it works !

Rob
Thanks for the offer for the PCB. I will use it to build another one.
Cause I just finished building my first one. I used perf board to hold the
parts. I substituted 50K pots for the 150K and 2K pots. So the tuning and
regen is rough. But as soon as I powered up, I heard a few US Shortwave
stations, including WTWW loud and clear. That's even without any antenna!
Lots of fun. Next I will order the correct pots and play with the coil and
tuning cap to put it in the 40 meter cw band.
BTW, The first thing that I heard on the rig was from station WTWW asking
for reception reports via email, and they will send you a QSL card. I sent
them mine!

The "resist pens" are simply Black sharpie permanent ink markers. You can get them any place where they have office supplies. Much cheaper :-) A hint for others who may want to try this… When drawing on your PC blank, make sure the copper is scrubbed clean, and that the ink goes on nice and black. you don't want to see any copper showing through where you draw. When etching circuit boards, I never had any luck with sharpie pens. Trying to make two layers of ink failed, as the second layer would erase the first.

I found that a good circuit board resist was latex paint. You can get an 8-oz sample from most hardware stores. Some of them have a color-error shelf, where the color didn't turn out exactly right and the buyer rejected it. These samples are cheaper still or sometimes free.

Use a toothpick or other fine pointed object to draw out your traces. Practice is helpful to ensure you make neat, organized traces. This isn't a necessity - look at PCB layouts from the 80s-90s, where the "traces" are blobs that cover most of the PCB. The hard part is getting in areas with close-together pins, such as DIPs and so forth. I'm sure that, with practice, someone could perfect it.

After painting, use a hot air dryer and blow on it for a while. Even though the paint may be dry to the touch, keep heating it. This hardens the paint onto the copper.

Etch.

Then you get to scrub the paint off the remaining traces. That's a lot of fun.

With laser printers as cheap as $30 and toner transfer there's no reason to screw around nowadays. The biggest problem is the trial-and-error required to develop a transfer process that works with your particular toner composition. Not wishing to spend 4-5X as much for authentic HP toner replacement cartridges, I've found good success with the yellow waxy-coated paper from Chinese suppliers and a $20 laminator using cheap replacement toner which has different properties.

Some use liquid photoresist or dry film but toner transfer is fast and simple and doesn't require exotic materials or playing chemist. Once I prove a concept I'll get professionally-made boards from China anyway, so I'm really only interested in prototypes and one-offs. If all goes well I can print and have a board ready for etching in under 10 minutes. If not...well, it gets frustrating sometimes!

The concept that does intrigue me most is direct laser printing, where toner (resist) is applied directly the PCB and then etched. This requires modications to the printer and an acetone vapor fusing process, so I have not tried it myself - anyone?

See Homebrew_PCBs@yahoogroups.com
for years of home brew advice.

The PANTUM p2502w driect print to copper is WELL documented HOW here:
https://www.instructables.com/id/Modification-of-the-Pantum-2502W-for-Direct-Laser-/

I have not gotten a round tuit yet but I did buy the printer.

As far as etch and hand drawing goes......
I laser print on cheap yellow transfer paper
then heat press toner transfer
http://www.learnmorsecode.com/laminator/hotcakes.html
http://www.learnmorsecode.com/regen/03batch1.jpg

With very consistent results.
I scrub my copper with very fine grit sand paper and then wash with acetone.
Then 3 minutes press time and sometimes have some missing toner transfer
spots that I clean up with
EDDING 404 instead of a sharpie.

I experimented with all sorts of inks...even found different colors
reacted differently within
product lines.

I experimented with an array of inks and nail polishes and concluded

KRYLON SHORT CUTSHOBBY and CRAFT ENAMEL SCB-026 gloss black

worked best if you truly could not purchase EDDING 404 pens.

The label says clean up brushes with lacquer thinner so I suspect that
this paint can be thinned with lacquer thinner and then used in a
drafting technical pen.
I have not ruined any drafting pens yet. More round tuit stuff.

Same here. I'd be interested in knowing how your conversion goes, as I'm not likely to get to it for some time. There'd probably be a market for already-converted printers if someone were to get the process down pat, as this is truly a "hack" (as in chopping out pieces!)

** I would think the choke should be left off as it raises the grid rf wise

Paul and Mike, i think, you are right. The rf signals on cathode and grid are in phase. This reduces the amplification as well as the isolation between antenna and the following regenerative detector. The rf inductor can pick up anything in the near and feed it into the preamp. It is much more sensitive in picking up, because oft it's high number of turns.

In my case, when i connected the grid directly to ground, i recognized vhf oscillation. A 220 ohms stopper resistor from grid to ground solved this. But instead of a triode i used a pentode in a common grid configuration, which isolates at least ten times better between anode and cathode compared to a triode. The pentode should have a seperate suppressor grid, so there are 2 grids connected to ground and the screen grid blocked by a capacitor. Care has to be taken, so the attenuated antenna signal is not able to cross over into the rest of the circuit. In my case on 20m band the rf potentiomer turned from 0 to 100% and back caused frequency shifts below 100 Hz.

Some data sheets are mentioning the Cac (anode to cathode capacity)
- Triode 6AB4: 0.24 pF
- Pentode 6BX6: 0.012 pF

Best regards,
Bernd

Probably because it’s not a grounded grid amplifier with the grid not grounded. A one-off success does not make an incorrect explanation good or guarantee repeatability.
There are leakage paths probably capacitive which conduct the signal to the preamp grid, since it’s above ground, or even beyond to the tuned circuit. It doesn’t take much.

I am curious about this GG issue.

Empirically, is any difference in performance noticed with or without
the choke?
Theoretically, how are the two differentiated? I wonder about
a "floating" grid grabbing sufficient leakage to behave like a GG.
As its main function is isolation, maybe it doesn't matter much
whether it is a real or "fake" GG? Sounds a bit like the debate
over the sensitive Kitchin "floating-diode" regen detector!

UK Intermediate exam passed today. The syllabus unfortunately
omits GG RF amps :-) The toughest bit : gotta think up
three pertinent yet-unchosen callsign letters...

Hi all, after selling my commercial receiver I am thinking of building a regen from a kit. After long browsing and surfing, I've seen this kit: http://www.kitradio.co.uk/page10.htm More, but not much info here: http://swling.com/blog/2016/03/the-krc-2-shortwave-regenerative-receiver-kit/#comments Not having a circuit diagram and more technical info, the only things I know about it are: - Sold by Kit Radio Company in UK. It appears the designer/producer s some Tony Westbrook, if that rings any bells to you. - Complete coverage 0-30 Mhz - One user commented: "So it’s a “supergainer”, which got lots of play in the thirties, the advantages of the superhet, but closer to the simplicity of the regen. People weren’t quite ready for a multiple stage IF strip, which is one reason the regen stayed around after the superhet came along" Again does it ring any bells? Is it a regen or something else? It's a fraction of the price of Mfj/Vectronics, etc, kits and it appears to be much simpler. Any input will be appreciated.

The circuit inclusive unwanted parasitics locks aproximately like this:
https://groups.yahoo.com/neo/groups/regenrx/files/Exchange/triode_preamp.jpg
https://groups.yahoo.com/neo/groups/regenrx/files/Exchange/triode_preamp.jpg

Cgc and C1 behave as a voltage divider, so the grid is not completely floating. Eventually the 4.7k resistor included between power supply and plate in combination with the low power supply are keeping the triode tamed.

27977. RE: [regenrx] Re: Kees Talen's "space charge" regen

Yahoo group: regenrx (2016 — 2017)
Date: 2017-04-24 00:36:28 UTC
From: Hubert Miller
Topic: 27965 Message: 27977

Reminder: the RF amp description from the author reads,
"I wanted the grid of the RF amp to have ONLY the bias level established by the 1K cathode resistor on it, not any potential RF from
the ground to "control" the signal, so a RF choke was added. You can also tie it directly to ground or through a x00K resistor but I believe the RF choke is better."

The circuit is on
http://www.qsl.net/k5bcq/REGEN2/regen3.html

which is on K5BCQ's website http://www.qsl.net/k5bcq/
which has a lot of really interesting reading and photos.

However the description quoted above is a bit iffy. The RFC raises the grid above ground by a very high impedance. Then you can redraw the circuit as a basic
grid input amplifier. The Cgk means some signal on the cathode will be coupled to the grid. The amplification of the grid input and the cathode input are out
of phase. Which one will predominate i can't predict. That's how i see it.

Thanks Howard,

If you don't mind, can you or anyone else explain what a fixed IF has got to do with a regenerative device?

Do I understand correctly if I say that this radio is a superhet with an added oscillator to increase its sensitivity? Is there any theory reference on this subject?

Thanks

On a closer inspection I found this forum thread:

http://theradioboard.com/rb/viewtopic.php?f=4&t=6973

Qrp-gaijin, which I believe is a member here, started the thread and Tony Westbrook injected some input, but not too much as this is a proprietary design.

There is a mention of freemodyne, whatever that means, but Tony did not either confirm or deny.

Dear amigos:

You are talking about a radio receiver circuit that is composed of two elements:

1. The front end , that includes the antenna input attenuator, the input bandpass tunable RF filter, the RF amplifier stage, followed by a mixer circuit that receives also a signal from a variable frequency oscillator. The output of the mixer is fed to the second element of this receiver configuration.

2. A second block of circuits that operates as a regenerative detector tuned to a fixed frequency... producing audio output that is fed to a standard audio amplifier circuit

In actual practice is known as a REGENERODYNE, using a fixed frequency regenerative detector, and a front end that uses a variable frequency injection oscillator

The second variation of the REGENERODYNE, by the way, the one I usually build for beginners that need a radio, uses a fixed frequency oscillator at the front end.... and the regenerative detector stage is then capable of tuning a certain frequency range... In actual practice , a regenerative detector operating from 2 to 3 megaHertz will work nicely using crystals for the front end to make possible tuning the short wave bands. Example, using a 5 megaHertz crystal, your radio will tune from 7 to 8 megaHertz... using a 12 megaHertz crystal, your radio will tune from 14 to 15 mHz etc....

That's the way to go, Arnie! It is a reproducible and responsive design
which lends itself well to experimentation with RF, regen and AF stages.
These can be on three separate boards for convenience.

Fremodyne is a VHF converter – superregen detector, for FM broadcast, in one tube.
The radioboard thread has some pretty silly questions asked about the KCR-2. Like noise floor and IMD compared to a straight regen receiver.
-Hue

>On a closer inspection I found this forum thread:

http://theradioboard.com/rb/viewtopic.php?f=4&t=6973

Qrp-gaijin, which I believe is a member here, started the thread and Tony Westbrook injected some input, but not too much as this is a proprietary design.

There is a mention of freemodyne, whatever that means, but Tony did not either confirm or deny.

The rationale for the non-grounded grid RF stage is that it works. Works, in that the signal does get thru it.

Well amigo... There is always room for experimenting by lowering the B PLUS voltage that feeds the regenerative detector tube, and also try using other tubes with different characteristics...

The very easy to reproduce circuit uses a single tuned circuit... leaving a lot of room for experimenting as regards to the tuning range...

Room also for a hybrid version, leaving the regenerative detector with the pentode vacuum tube and using a solid state audio amplifier...

With the voltages shown on the circuit diagram, the regeneration control is as smooth as silk... no plops or clicks... just a swift in and out operation as the circuit approaches the point where it starts to oscillate....

Another area for experimenting... add an antenna coupling link, that has a 1 kilo-ohm carbon control connected so that it acts as an RF input gain control... Of the three legs of the potentiomenter one goes to ground, the top goes to the top of the link coil, and the antenna is connected to the center of the control by means of a ceramic or mica capacitor... finding the right value depends on the frequency range of the regenerative detector...

By the way... this circuit is an excellent TAIL END for a Regenerodyne receiver... using the frequency range from 2 to 3 megaHertz, and several quartz crystals for the front end converter your radio will tune in one megaHertz segments... For example... a 5.000 mHz crystal will make possible receiving from 7.0 to 8.0 megaHertz..... a 12.000 mHz crystal will make possible to receive from 14.0 to 15.0 mHz and TUNING BACKWARDS.. you can listen to 10.0 mHz to 9.0 mHZ (the very popular for SWL broadcast listening 31 meters band...

Hola Arnie, thanks for posting the schematic! Some questions, please… I understand the box is the European schematic symbol for a resistor. But what do the dashes inside the box mean? Some straight, some slanted… Wattage rating?
It looks like the output transformer has a tap, but I think maybe this is not a center tap?

Arnie mentioned:

" .. using the frequency range from 2 to 3 megaHertz, and several quartz crystals for the front end converter your radio will tune in one megaHertz segments... For example... a 5.000 mHz crystal will make possible receiving from 7.0 to 8.0 megaHertz..... "

Very true. I recommend using the very common surplus 10 MHz xtals for 7.0 mHz, basically because you stand less chance tuning in that 5 MHz LO at the front end. Our local Orlando milsurp usually has a full drawer filled with 10 MHz xtals in an assortment of sizes. Especially HC/6, which works nicely in the grid of a 6C5 LO. But the 5 MHz xtal works well, too.

R7 WOOPS ! My mistake... it is a 47 ohms anti parasitic oscillations resistor... A 47 k will reduce the input audio level to the grid of the triode section of the triode-pentode.

My now standard audio modules are done in two configurations (depending on the parts available)

Module A: Uses a ECL82 / 6BM8 with excellent results, no need for tapped transformer, but I do add a .1 mfd 600 v polyester bypass capacitor from screen to ground...

Module B: Uses 6AU6 of similar audio preamp, and EL84 audio output...

Then later Module C: came to life including simple audio filters...

> Add capacitor in parallel with the main tuning C2 for bandspread tuning.
C1 Antenna coupling capacitor 1 to 5 pF
You can also use a link coil on the same coil form to feed the RF from
the antenna by inductive coupling

The test below the 6AK5 says: Highly sensitive regenerative receiver
with Soviet made vacuum tubes (valves) that are available in Cuba

FURTHER IMPROVEMENTS: Use 6.0 volts regulated DC voltage to feed the
filaments of the 6AK5 tube
Regulate the feed voltage to the screen grid regeneration control... the
150 k potentiometer can be changed to 100 k or 50 k and using a series
voltage dropping resistor...
The coil L2 is open for experimentation ... typical distance from the
main grid tuning coil , about 1/8 of an inch or 3 mm... If no
oscillation is achieved, just reverse the connections of the plate
feedback winding.
Another area for experimenting: The C2 and R1 parallel network...
Sorry, can't remember right now the meaning of the line inside the
rectangles that represent carbon resistor... My regeneratives using this
16 passive electronic components plus one vacuum tube , use coils wound
using 1 inch or 25 mm cuts of white PVC thick wall pipe.

The B+ voltage is 160 volts. That is possible without a power transformer in the power supply. Because 117 volts RMS is 160 volts peak to peak, and therefore all you would need is some filtering on the power supply. A low power fuse would be nice as a safety precaution. Does anyone have a circuit for a 160 volt, no transformer, low currrent power supply?

To: regenrx@...

A part of my Dxers Unlimited radio hobby program to be on the air today... The idea is to promote listeners to build their own radios and accesories... All I can say is that it does work, having had the pleasure of receiving many e'mail messages and letters describing home built regenerative receivers... both vacuum tubes and solid state versions...

73 and DX

Arnie Coro CO2KK

From Dxers Unlimited's script for the 25th of April show...

Just a few days ago, I was asked by a long time Dxers Unlimited listeners if it would be possible to design and build a minimum parts count vacuum tube regenerative receiver that could provide good performance .... Quite a challenge amigo Carlos, I told him, but it can be done.... so I went to my paper archives and started to look at all the circuits , keeping in mind that the request required maximum simplicity, that is minimum number of parts, but also good performance... Of the many circuit diagrams and notes found, it was clear that a single tetrode or pentode vacuum tube with high enough gain could do the job... The SIMPLE REGENERATIVE, will require the use of high impedance headphones , an operating voltage not higher than 90 volts, and if possible no more than 40 to 50 volts... It was also quite clear that the Hartley circuit was possibly the best choice, and that screen grid regeneration control will be an easy approach to the critical control of the vacuum tube's operating point... Well to make a long story short to fit into today's show, all >I can say is that the SIMPLE REGENERATIVE, started to pick up short wave signals just after soldering the last connection. I was running the experimental setup on a gel cell rechargeable battery for providing the filament voltage to the 6AK5 tube, by tapping the battery at the end of the third cell, and the high voltage came from my home brew multi purpose variable voltage bench power supply... I could run the radio at an amazingly low plate voltage of just 25 volts and still be able to receive several short wave broadcast stations on the 49 meters or 6 megHertz band... The audio output volume while running 50 volts on the plate of the 6AK5 was really

good, and after winding the coil for tuning on the 40 meters band it was possible to pick up several Cuban radio amateurs during the daytime Near Vertical Incidence Skywave propagation mode.
The only two critical parts of this minimum parts count experimental radio are the air spaced variable capacitors.. One is the main tuning control , and the other is used as a bandspread for precise tuning of the narrow CW and Single Side Band signals... You will want a good quality potentiometer for the screen grid voltage control and follos standard practice when assembling a receiver's tuned circuit, that can be resumed by saying, build it like a battleship... with heavy wire connections and proper mechanical mounting for the variable capacitors... Now let me add that having had the opportunity of experimenting with this Hartley or cathode tap regenerative receiver using several miniature seven and nine pins pentodes, I found several of the more modern tubes that came out during the best years of the vacuum tubes TV sets, that would receive signals on the AM medium wave broadcast band with plate voltages as low as 12 volts.... Fortunately there are no rare or unobtanium parts used in this simple vacuum tube regenerative receiver... But at least one of the builders here brought out to my attention the fact that the plate and screen grid current of the regenerative detector tube are going through the coils of the magnetic earphones... so Emilio suggested to use a high quality audio output transformer to feed the tube and then connect a pair of high quality, sensitive headphones to the secondary winding of the transformer...My pair of Russian made 2000 ohms impedance headphones work well when used with the high voltage going through them, but Emilio was right in pointing the fact that using a good quality audio output transformer and low impedance headphones will prevent damage to the high impedance headphones in case a short circuit condition happens at the plate circuit of the detector tube... Now for the parts count.... when you start listening to this radio and take a look at the breadboard where the prototype was built, it is simply amazing that it is capable of such a good performance... I do missed the lack of a volume control, to one more potentiometer was added at the antenna input... so now , when listening to the AM broadcast band stations I can just move the antenna gain control to the point of more comfortable reception...
Listen now to the number of parts used : including the home brew tuning coil.... MAXIMUM 20 parts including the required bypass capacitors... Of course that you can test the radio with just one tuning capacitor, and do not use the RF antenna gain control... but adding the bandspread tuning capacitor and the RF gain will improve the performance. Also finding a good quality multi tap audio output transformer may be diffcult nowadays, but it is a worthwhile effort to search for one...
Now, Emilio is building a second SIMPLE RADIO, that as he says is no longer so simple, because he is adding one audio amplifier stage and an audio volume control too.... Si amigos, sure, listening to your own radio based on the early days circuits is quite an experience, especially after you find out how sensitive and selective this radio can be...If you are interested in learning more about this SIMPLE REGENERATIVE receiver

But at least one of the builders here brought out to my attention the fact that the plate and screen grid current of the regenerative detector tube are going through the coils of the magnetic earphones... so Emilio suggested to use a high quality audio output transformer to feed the tube and then connect a pair of high quality, sensitive headphones to the secondary winding of the transformer...My pair of Russian made 2000 ohms impedance headphones work well when used with the high voltage going through them, but Emilio was right in pointing the fact that using a good quality audio output transformer and low impedance headphones will prevent damage to the high impedance headphones in case a short circuit condition happens at the plate circuit of the detector tube... Now for the parts count.... when you start listening to this radio and take a look at the breadboard where the prototype was built, it is simply amazing that it is capable of such a good performance... I do missed the lack of a volume control, to one more potentiometer was added at the antenna input... so now , when listening to the AM broadcast band stations I can just move the antenna gain control to the point of more comfortable reception... Listen now to the number of parts used : including the home brew tuning coil.... MAXIMUM 20 parts including the required bypass capacitors... Of course that you can test the radio with just one tuning capacitor, and do not use the RF antenna gain control... but adding the bandspread tuning capacitor and the RF gain will improve the performance. Also finding a good quality multi tap audio output transformer may be diffcult nowadays, but it is a worthwhile effort to search for one... Now, Emilio is building a second SIMPLE RADIO, that as he says is no longer so simple, because he is adding one audio amplifier stage and an audio volume control too.... Si amigos, sure, listening to your own radio based on the early days circuits is quite an experience, especially after you find out how sensitive and selective this radio can be...If you are interested in learning more about this SIMPLE REGENERATIVE receiver

Here is my question. We can, and in fact did, read the designer's "bullet points".
As an EE, what do you say about this 'bullet point' explanation ?
What would be a "sensical" comment about this "bullet point" explanation?

"I wanted the grid of the RF amp to have ONLY the bias level established by the 1K cathode resistor on it, not any potential RF from the ground to "control" the signal, so a RF choke was added. You can also tie it directly to ground or through a x00K resistor but I believe the RF choke is better. "

I would characterize the above explanation as "armchair theorizing". The 'bias level' is DC bias and this doesn't care whether the grid has a choke, resistor, or jumper wire to ground. The cathode resistor ONLY defines the bias.
Raising the grid above ground cannot eliminate "any potential RF from ground".
You do get what we're questioning, right ?
Bernd got it right when he said the high impedance at the grid would NOT isolate the grid from input RF.
What say you, as an E.E. ? Accept the statement verbatim, and move on?

Many circuits 'work' because they work, somehow, despite how the designer "believes" it works. . If the only criterion is that they somehow work, okay. Yes, the circuit meets the design criteria, which is, that "it works".

You seem to dislike analysis and criticism here of circuits. I'm sorry, but this is not just a venue to praise people's projects. You are not the first to be mistaken about the purpose of the discussions here and to think circuit
analysis is somehow beyond the pale.

Subject: RE: [regenrx] Re: Kees Talen's "space charge" regen

Hue. You totally missed the point I was making.
The bottom line is always whether it works per the designer's criteria and not the intellectual, armchair theorizing and guessing by lazy opinion makers who don't actually build and test circuits but 'troll' out nonsensical comments.

In addition, my comment(s) were directed to folks who are too lazy to read the designer's notes...rationale(s), or understand plain english. BW

While simulating the circuit, it broke into oscillation. it behaves like a TPTG oscillator. No wonder, to grid and plate are equal coils connected with similar resonance frequencies. Oscillation starts already with 4 Volts on the plate.

With included stopper resistor the amplification is still as high as 4-5 times, also because the plate voltage can be fully increased to 12 volts without self oscillation. Then the coupling capacitor between preamp and detector stage can be reduced to 1pF...

I have sent a message to Kees and asked him niceley about his opinion.
Does anybody know, if he is a regenrx member.

Bernd, excellent point about the TPTG, which i had not noticed. A triode tube with resonant circuits in both grid and plate circuits. That is asking for trouble.

From: Hubert Miller
Topic: 28006 Message: 28006

I tried kicking the dog, as suggested, but it bit back, so i’m still being hypercritical and picky. I’m sorry.
Have a look at the last photo, the underchassis layout, and tell me this is good RF practice.
Note the length of the wire from the switch S1 to the atten pot.
And why put a switch, to switch tube contact pins, in an RF amp stage ??
That’s just asking for trouble!
Note the proximity and positioning of the choke coils.
No wonder an “RF Set” control is needed!
Also contrary to the description, the circuit does not work as a “diode detector” when the “RF Set” control
is not positioned correctly. It may detect on strong signals, but not as a diode detector. If you disagree, tell me how
it functions as a diode. Biased detector (“plate detector” or “power detector”) maybe.

I didn’t tap his internet line or pry into his life to observe the above.
It is all publicly published; we are invited to read it.
I do not have to agree with it.

28012. pF capacitor tester

Yahoo group: regenrx (2016 — 2017)
Date: 2017-04-26 17:10:56 UTC
From: Rob
Topic: 28012 Message: 28012

I was playing with 5pF ceramic capacitor replacement with a gimmick capacitor
when I concluded that none of my digital meters would go down into PICO farad land
so I got a M6013 capacitor meter and tested the capacitors used in the KITCHIN regen.
http://www.learnmorsecode.com/regen/00regen.html

I was curious to so if the capacitors that cost half a penny were even close to their
marked value.

They all were:

http://www.learnmorsecode.com/parts/index.html

There have been doubts and mistrust in the Chinese cheap components but so far I
have not been disappointed by these dirt cheap components.

1,000 capacitors for $7
1,000 resisters for $10
1,000 2N2222 transistors for $7

The RADIO SHACK prices.. $2 for 5 resisters..... was a mugging.

All the parts I used that heard France and Cuba cost less than a beer.

From what i have read, the imported parts problems only intrude in the area of chips, IC’s. Then there have been some used – recycled, or second-grade relabeled. I read one article which even reported that some Chinese
relabeled chips had gotten into U.S. defense department electronics.
A few years back, i had a number of experiences with terrible quality control in Chinese products; it seemed the only goal was to
make a sale; if the product didn’t work out well, well, that’s just tough. It seems that era is over, thankfully. Maybe that had to be
part of China’s bootstrapping, industrialization process, which they climbed very rapidly.

My brother builds large LED assemblies for plant nurseries and he’s steadily buying LEDs and power transistors and power switch
circuitry from Hong Kong and China and he is constantly astonished at the low prices. Sometimes a price will be around $5 – or less !
and – the postage is INCLUDED – i mean price is inclusive – from China. __

My rule of thumb: 1cm of gimmick capacitor equals 1pF.
It depends a little bit on the wire diameter and how tight it is turned together.

28017. Morsum Magnificat goes online

If you're interested in anything to do with telegraphy or radiotelegraphy, you might want to bookmark
http://www.n7cfo.com/tgph/Dwnlds/mm/mm.htm
and check it from time to time. There are also indicated 'Index Issues' which periodically indexed a recent
range of dates.

This is a generous offering, scan project for Morsum Magnificat magazines. There were numerous articles
on wartime radiotelegraphy, clandestine radio use, and such.

I gave away most of my copies years ago and then sort of regretted it. Now comes this site to the rescue.
Note, it's a work in progress; copies are still to be scanned in. We can be thankful for generous hobby
colleagues who kindly do this work to share the interest.

From: Phil
Topic: 28018 Message: 28018

I'm not sure if it was on this list, or the Softrock list (both do a lot of construction), but awhile back somebody was discussing checking small capacitor values, and one individual posted a picture of the capacity tester they used.

Well, I too do a lot of constructing, and in fact am presently building another Softrock Ensemble II LF. Lots of toroids to wind as well as a lot of capacitors with values indicated with itsy-bitsy writing that requires the use of my Forehead mounted magnifier combined with the lit bench magnifier to read. When I wind the toroids I like to test each one for value to double check my turns count.

Rather than buy a single purpose meter, I decided to buy a LCR meter (measures inductance, capacitance AND resistance, though I much prefer a DVM for the latter.

This is the one I bought back in August 2015, and it's done yeoman service in my constructing. NOT a bad price either. . .
https://www.amazon.com/gp/product/B00GYT5WL8/ref=oh_aui_detailpage_o02_s00?ie=UTF8&psc=1

By the way, I reviewed the product back in 2015 after I'd used it for some time.

I bought an even lower priced one a couple years back figuring i had little to lose, and i have been extremely happy with it.
The Chinese test instruments with built-in smarts are really kind of amazing (assuming you get a good one) and the free
shipping, priced like a local sale. I have been looking at sweep generators lately and one of those is next, maybe.

If you get yourself one of these LCR meters, and then one of the semiconductor identifier-analyzers for not much more
money, well, then you are really set for success.

The 100H inductor range on this set is well chosen and covers just about every choke you're likely to encounter in power supplies,
and transformers also. I have some 400 Hz power transformers i removed from a microwave signal generator and i was able to
verify that these would make good receiver chokes for old-time circuits, as they were in the range 30 to 50 H.
I have sometimes wanted a higher end tester for some of those old-time receiver chokes that go into the
several hundreds of Henries, but if i need to do that, i suppose i can rig up an audio generator and resistance box and voltmeter
and do it the harder way.

Thanks for posting the link and reminding me of this! I might even do a slight "upgrade" to this set.

From: Hubert Miller
Topic: 28026 Message: 28026

Look, silly question, but bear with me.
I just want to order 4 of 3.3 megohm (3m3) resistors, thru hole, just ordinary old carbon.
I don't want a $25 minimum charge i see only after i go to the cart; i don't want to order a resistor kit, and i don't want to
see a list of manufacturers, leading to spec sheets, before i choose.

What is the simplest way to order only 4 of these simple parts? I would be okay with some kind of minimum charge, but not
$25.
(This is to replace a 4.5 volt bias battery BA-1293/U in an Army radio. I want to just use a regular 9 volt battery with a voltage
divider of 2x 3.3M to give 4.5 volts. There is no circuit drain on the bias supply, it goes to a 3Q4 grid; and the voltage divider
drain on the 9 volt battery will be microamps, so it should last years, even longer than a smoke detector battery.)
thanks-
Hue

What Wattage?

I have three Ohmite variety selection boxes. Say the word, and it's on the way to you (if I have it - I haven't looked yet.

The minimum order is $0.00 with free shipping.

From: Hubert Miller
Topic: 28026 Message: 28029

I neglected to explain, there is practically no power thru the resistors. The drain to set up the bias, i decided arbitrarily to be 5 uA or less.
I think a couple of 2M or 3M resistors would be fine 1/8 or 1/4 watt. I said qty=4 because i have a second of these transceivers that needs this done,
eventually. The original battery is a unique based plug-in, not available. The one i removed and took apart, to see what's inside, had
3 mercury cells #625 strapped in series. The date code seemed to be 1963.
Just a couple of the resistors would set on my way on this project.
I would still like to know the answer tho, on small quantity parts orders without having to deal with a large minimum charge,
resistor packages, or having to sidestep lists of manufacturers and package specs.

Hello,

The resistors are Ohmite " Little Devels " and I have one each 2.7 meg and 3.9 meg, all 5 Watt resistors and only one each. I spoke too soon. In these variety packs, there is no 3.3 megs.

Try finding a Radio Shack store still open - some are clearing out their parts depts. You might get lucky there.

Sorry I spoke too soon.

Also, on older resistors like these, keep in mind that they tend to drift upward in value with age.

73,

Sam Neal N5AF

I like https://www.banggood.com
1000pcs 100 Value 1/2W Carbon Film Resistor Assortment Kit
for $10 and free shipping because
1/2 W carbon resistors have stripes big enough to see on the tan body
compared to
blue metal film resistors or 1/4 or 1/8th watt resistors.

I store them in coin bottles in a tool box:
http://www.learnmorsecode.com/parts/zresisters.jpg

which makes for rapid parts selection when following a schematic for a
build.

I got an inquiry WHATS UP WITH ALL THOSE DAMN ALIENS

They are not aliens. They are extra prototyping pads
http://www.learnmorsecode.com/regen/04bottom.jpg

I found that often the additional output capacitor or
fine tuning capacitor needed some PCB landing anchor so
I always leave additional 3 hole pads for prototyping tasks.

28035. Screwdriver adjust, locking var caps - repurpose ?

Yahoo group: regenrx (2016 — 2017)
Date: 2017-05-02 05:47:06 UTC
From: Hubert Miller
Topic: 28035 Message: 28035

(I don't recall if i included this question to regenrx as well as another group.)

"Single bearing, locking shaft, screwdriver adjust variable capacitors."
I harvested around 20 out of a boat radio antenna coupler. These are real nice and clean around 200 pF variables.
They are single-hole mounting. The shaft bushing is tapered and split near the end so a second smaller nut on the
bushing, locks the shaft from turning. Only about 1/8 inch of shaft protrudes beyond the shaft bushing; not enough
to attach any kind of knob to.
How to use these? I know that as single-bearing caps, they are not stable enough for VFO use. But i would like to be
able to use them for something.
If i superglue a shaft extension onto the shaft end, do you think that joint will be strong enough to hold?
There is not enough shaft protruding to use a shaft coupling.
If i saw down the bushing length, it ruins the mounting thread.
These caps are stiffer to turn than the usual broadcast radio cap.
I would like to figure out a way to repurpose them for true variable use, not adjust and lock in place.
thanks-
Hue

Topic: 28035 Message: 28036

I would drill into the shaft and thread it.
Then screw in an extension with super-glue or similar.
If sturdily built, as I would assume, given their provenance,
they might well be suitable for a VFO. In extremis, I would
extract the moving vane part and lightly sand the shaft down.

Even if it would not seem worth the effort - the challenge
certainly is! With a bit of luck DT will ban varicaps :-)

Ah, I have momentarily realised that I have a few amongst
the cobwebs in the j-box. Maybe one day...

Tell Mouser when ordering to ship them First Class Mail (not Priority). If the package is 13 ounces or less you're only going to pay around $3.00 shipping. And in my opinion it's faster than UPS which they usually use. I just received an order placed that way and shipping was only $2.61.

28040. diode substitution in RF probe D9B to D9J

Yahoo group: regenrx (2016 — 2017)
Date: 2017-05-02 16:08:43 UTC
From: Rob
Topic: 28040 Message: 28040

Don't know.....see
http://www.ebay.com/itm/122471544241

I'm a little foggy on this subject.
I had asked a month ago when I bought them... now that they arrived I am revisiting learning what I have in my hand.
The standard Digitial Volt Ohm Meter with a diode tester says 0.32 to 0.36 volts on all I have tested so far.

They definitely work in the KITCHIN regen circuit.

I'm not sure of the usefulness of each type of diode.
I only have the goal of simple crystal radios and RF "detector" circuits .... regen front end....

I have D9B,D9K and D2D now and waiting on D9E and D9J... usually a few weeks shipping.
All have worked so far in my simple radio projects.
And they cost less than 5 cents.
So that makes them a good candidate for kids ... scouts... newbies... projects.

I was very surprised to see voltage ratings above 30 volts.
I thought the 1N34A became the standard at 30 volts.
So 50 and 100 volts just looked way out there.

D9B USSR Germanium Detector Diode 10V 40ma 100 KHz
D9K USSR Germanium Detector Diode 30V 30ma 100 KHz
D2D USSR Germanium Detector Diode 50V 16ma 150 MHz

D9E USSR Germanium Detector Diode 50V 20ma 100 KHz
D9J USSR Germanium Detector Diode 100V 15ma 100 KHz

It's not easy to drill a hole in the exact center of the shaft.

If the shaft is brass or steel, it would be better I think to lightly tin the short stub with solder. Then use a brass or bronze coupling (and decent hardware stores usually stock bronze bearings for electric motors) with the appropriate inner diameter. Tap one end of the coupler/bearing transversely for a set screw if you want your shaft extension to be removable. If that's not needed, then use 1/4-inch brass rod (available in three-foot lengths from Lowes, and maybe Home Depot) for your extension. First solder the coupler to the short stub, and then solder the extension into the outer end of the coupler. From where the solder is applied at an opening, capillary action will suck molten solder toward the heat source.

Charles

Valid point, Charles. I envisaged using a drill stand.
As stated, I would only attempt it in extremis. Your suggestion
using a coupler to minimise the strain on the soldered stub-joint
certainly has a good chance of success. But, again, the challenge
would have to merit the effort.

Speaking of the olde BC radios, the audio stages of filament type tubes often had a device riveted to the chassis wall and marked on the schematic as BC-1 or BC-2. They were (not sure that I kept one) a small cup with an insulated metal arm pressing on what looked like a carbon slug within that cup. In the 50s, these units from the 1930s still registered a volt and a half with a high resistance meter. I am sure there is more information on the Bias Cells of yesteryear within this group. The receivers that came my were in fact Rogers Majestic units. One battery powered and the other transformer powered. The battery radio needed a two volt wet cell plus three B batteries which were beyond the resources of a 12 year old. The AC operated unit was a joy to operate in the quiet environment before TV came to the farm. 73Gordon VE5UJ

As did a lot of the (10 plus tubes) early Rogers BC radios.

28045. Does the direction of the germanium diode matter?

Yahoo group: regenrx (2016 — 2017)
Date: 2017-05-03 01:05:15 UTC
From: Rob
Topic: 28045 Message: 28045

Does the direction of the germanium diode matter?

AA7U pointed out that my regens all had backwards mounted germanium diodes:
I'm not real surprised. My vision is impaired.

http://www.learnmorsecode.com/regen/03REGEN.jpg
http://www.learnmorsecode.com/regen/04top.jpg

My mistake was because I thought the red band denoted the cathode
but
nope
So I did the diode testing and concluded that D9B...red stripe
and D9K ..white stripes ... are on the ANODE side
and the D2D ....yellow blue black has yellow on the ANODE side and the
black on the CATHODE side.

http://www.learnmorsecode.com/regen/diodesstripes.jpg
http://www.learnmorsecode.com/regen/diodestripes2.jpg

So this raises the question of......
Does the direction of the germanium diode really matter in this circuit?
http://www.learnmorsecode.com/regen/00KitchinREGEN.jpg

ALL of these circuits heard Professor Arnie Coro 1,300 miles away in Cuba.

Hi
I suggest you bring out the Diode connection(s) to Banana Jacks, Binding Posts or Fahnestock clips
so as to be able to easily reverse the Diode and see if there is any difference.

Are you sending me parts to transship to your friend in the USA?

In anticipation of not knwoing how well each type of diode would perform
I made version ONE
with NIXIE tube sockets for the 1N34A diode.... which I swapped out with
a D9B diode:
http://www.learnmorsecode.com/regen/00kitreg02.jpg
http://www.learnmorsecode.com/regen/00kitreg05.jpg

I use WIREWRAP pins and NIXIE tube sockets to custom make cable connectors.
NIXIE tube socket pins mate loosely with WIREWRAP pins so they have to
be pinched a little to
make them mate firmly.
The idea is to have external board components easily swapped for
experimentation.

A counter-suggestion; Brazing is a LOT stronger than solder, if you can arrange that (or some mechanical coupling collar) that might last a lot better than solder. Or even try JBWeld or the like :)

I agree that brazing is much stronger than solder. But, please, what is presented is not a high-torque, nor high-speed, rotational situation. Gentle and slow hand movement would really be the extent of the force being exerted upon a well-soldered mechanical junction.

If you believe otherwise, then after doing the solder job I've already described, drill a small hole transversely through the soldered junction at its maximum diameter and drive a small soft steel pin, e.g., a small nail to fit tightly in the drilled hole.

Charles

Topic: 28056 Message: 28056

Radio Havana Cuba
Dxers Unlimited weekend edition for Sunday 7 May 2017
By Arnie Coro
radio amateur CO2KK

Hola mis amigos radioaficionados that are now listening to the weekend edition of Dxers Unlimited...I am Arnaldo, Arnie, Coro radio amateur CO2KK, your host here at the one and only radio hobby program on the air and on the web providing coverage to every one of the more than 90 ways of enjoying this wonderful hobby....RADIO. A quick check shows that more and more radio amateurs are using sophisticated digital communications modes that require the use of really high performance computers... Other ham operators that run older machines still have the option to use the easy digital mode... PSK31 and its higher speed versions like PSK63 and PSK125... and here is today's program first topic...Radio amateurs in the Caribbean region, Central America, Mexico and the Southern United States are getting ready to deal with the upcoming Tropical Hurricane Season, due to start on the first day of June, although this year a very rare tropical cyclone developed out of season, surprising scientists that carefully tracked the storm... So far I have not heard about the season's forecast that is published every year ahead of the start of the six months long period that spans from the first of June to the end of November... Preparations for providing emergency communications is at the top of the list of activities by Cuban radio clubs .
Item two: Amazing two way amateur radio contacts on the 80 and 40 meters bands are happening almost every day while using power outputs into the antennas of one Watt of even less. Minimalist transceivers that use the output power transistor as the receiver input product detector have shown that when propagation conditions are normal or above normal, two way contacts can be made using such low power rigs that follow the design criteria of the minimalist PIXIE transceivers . Si amigos, yes my friends, a low parts count little transmit and receive capable home assembled rig when connected to an efficient antenna will be able to establish long distance contacts ...
Item three: Answering a question sent by listeners from Australia... that wanted to know more about the DRM Digital Radio Mondiale system... Yes amigos, it is exactly what is happening, what continues stop to a standstill the introduction of DRM is certainly be the lack of low and medium cost receivers capable of picking up DRM signals And yes, we have confirmed from two independent source that about an integrated circuit capable of demodulating all possible transmission modes, including standard AM, FM, and several of the already on the air digital radio modes, like DRM, the IBOC or HD Radio and all different DAB modes....is expected to the licensed for production by several IC manufacturers . As

expected massive production of this new digital integrated circuit that automatically detects the modulation mode in use , producing clear audio output, could be the much needed breakthrough every one is expecting in order to introduce the most efficient digital modes at a worldwide scale....
Now from Dxers Unlimited's weekend edition... a short form solar activity update.... The Sun is once again going through another period of very low activity, but for the past several days we have seen sunspots every day...
Each of the weekly solar and geomagnetic indicators that are tracked were lower this week. Average daily sunspot number dropped 10.6 points to 25.1, and average daily solar flux was 4.5 points lower than the previous week at 76.9.
It is comforting to see though that we have not witnessed a day with 0 sunspots since April 17. Average planetary and mid-latitude A index were both 5.6, down from the previous week which had planetary A index at 26.4 and mid-latitude at 18.4. The A index is expected to remain quiet until May 17-20.
Stand by now for a few seconds as we go to a break for a station ID. I am Arnie Coro in La Habana Cuba

short musical intercut

This is Radio Havana Cuba, the name of the show is Dxers Unlimited, and yes amigos we are very proud of having helped many short wave listeners around the world learn about the existence of amateur radio, leading the way for many of them to now own and operate their own amateur radio service stations to communicate across town on two meters or half way around the world on the most used DX band... 20 meters.... By the way, I enjoy a lot calling CQ DX on 14 060 kiloHertz using slow speed hand sent Morse Code Radiotelegraphy while running 5 Watts or less into a wire antenna that was made from recycled wire coming from a burnt out power transformer primary winding. The three insulators required were made using poliethilene flexible garden hose stock of three quarters of an inch diameter.... That is a low cost antenna by all comparisons... because it is fed using a two wires balanced transmission line also made from the same recycled wire and insulators for the ladder type feed line cut from the same length of poliethilene garden hose. As I have said it here many times.... amateur radio need not be an expensive hobby at all, and my dipole antenna is just another example... It is cut as a full size 60 meters band half wave dipole, and tunes easily from 80 meters all the way up to the 10 meters band, and let me add that using a second antenna tuner especially made for the six meters band the antenna works nicely on the 50 megaHertz band too...
5 watts CW on the 20 meters QRP calling frequency 14060 kiloHertz has made possible contacts as far away as New Zealand under good propagation conditions, and as expected many replies to my CQ calls from CO2KK are received from the first skip zone of 20 meters that spans for around two to three thousand kilometers away from La Habana, Cuba where my station is located. Whenever very short skip is present on 20 meters , I just move to the six meters band and start calling CQ DX, because the very

short skip on 20 meters is a very good indicator of possible sporadic E openings on six meters. Let me insist on something said earlier this week....Amateur radio operators having stations capable of operating on the 10 and 6 meter bands will be able to make many DX contacts on those two bands during the summer Sporadic E season that is now starting... But.... the real challenge brought by Sporadic E layer events is that so far they have proven to be impossible to predict... there is no known forecasting method that can tell in advance when one of such super density sporadic E layer patches starts suddenly bringing in DX signals for periods as short as a few minutes or maybe even hours and then suddenly just vanish...And let me also insist on the fact that for 6 meters band operators the sporadic E events make possible working DX stations several hundreds of miles away, with the first skip zone area coming after a zone of no signals... There is also the possibility of double and triple hop skip signals when two or three patches of high density sporadic E clouds align themselves properly...
And now at the end of the program here is our propagation update and forecast for the next several days--- solar activity still at very low levels, just a few weak sunspots active regions in sight Saturday morning local time here in Havana.... 14 hours UTC... when I was typing the script of this program you are listening to right now. Be on the look out for more sporadic E openings... it is now clear that the late spring and summer E skip season is well under way...AMIGOS please don't forget to set aside a little time to send me a signal report and your most appreciated comments and radio hobby related questions to Dxers Unlimited. Send mail to inforhc at enet dot cu ... Via Air Mail to Arnie Coro, Radio Havana Cuba, Havana , Cuba

Pretty interesting little site, thanks!
I agree that the homemade variable cap is just too much work!
I enjoyed reading about the SW loop set. Author's comments on excellent results mirror Don's (VE3....) posts here about his loop sets, also reminds me of the "Jade Products" 40 and 80 meter
loop receiver kit from a few years back.

Here is a question. On the variometer tuned circuit shown in URL below, is suggested to make the coil form out of a band of stiff plastic. I need to make exactly such a coilform to restore an old
kit radio from 1960. The coil is around 8 inches in diameter, it's actually the pickup loop antenna. The old plastic form is deformed and weak. Anyone suggest a source of fairly stiff sheet plastic
that can be bent into a circle and glued, and will hold its circle shape? thanks-
Hue

28059. 250 and 750 volt power supply questions

Yahoo group: regenrx (2016 — 2017)
Date: 2017-05-10 02:07:57 UTC
From: Rob
Topic: 28059 Message: 28059

I have an upcoming tube project that defines its power needs as
6.3 volts and 250 volts and 750 volts.

Its been 16 years since I rebuilt a tube rig power supply so I have some
questions.

Here is a HEATHKIT HP 23 power supply schematic:
http://www.learnmorsecode.com/regen8/hp-23-schematica2.jpg

If I had this power supply..... or ... more likely.....the parts to
build it... from the bottom up...

1. could I LEAVE OUT the PURPLE 12 volt wire?

2. could I LEAVE OUT all of the RED bias components?

3. could I hardwire all of the YELLOW 250V circuit to the 95 VAC?

4. could I knock down the GREEN 820V circuit to 750V by adding the
BLUE string of 1N4007 diodes?

5. If I could not obtain the original transformer then would it be OK
to use three transformers
for each of the original voltages of 268 volts and 95 volts and 6.3
volts.....
and tie each of the MINUS ground side of each of the DC circuits together ?

Subject: [regenrx] 250 and 750 volt power supply questions

I have an upcoming tube project that defines its power needs as
6.3 volts and 250 volts and 750 volts.

Its been 16 years since I rebuilt a tube rig power supply so I have some questions.

Here is a HEATHKIT HP 23 power supply schematic:
http://www.learnmorsecode.com/regen8/hp-23-schematica2.jpg

If I had this power supply..... or ... more likely.....the parts to build it... from the bottom up...

1. could I LEAVE OUT the PURPLE 12 volt wire?
----Interestingly, that transformer output is 12.6V CT, so you could use either 12V tubes or 6V tubes. If you want to use only 6V tubes, it would be good (but not required) to balance current in each leg of the transformer secondary by using the same number of tubes on each side. Of course, you need to take into account the total current required, what is available, and not exceed it.

2. could I LEAVE OUT all of the RED bias components?
----If you do not need any negative grid voltages.

3. could I hardwire all of the YELLOW 250V circuit to the 95 VAC?
----Yes, it is shown as an option. The 1N4007 diode (1000V PIV) is the one to keep spares in your junk box. they are cheap too!

4. could I knock down the GREEN 820V circuit to 750V by adding the BLUE string of 1N4007 diodes?
----The circuit is a voltage doubler, and should develop about 1.41xVsec or about 758VDC, where Vsec is the secondary RMS voltage of the transformer. The circuit will require only a single 1N4007 diode in each leg of the circuit, not two.

5. If I could not obtain the original transformer then would it be OK to use three transformers
for each of the original voltages of 268 volts and 95 volts and 6.3 volts......
and tie each of the MINUS ground side of each of the DC circuits together ?
----Yes, each winding is independent, you are only referencing them to the single point. The currents in each circuit are returned to their respective supply.

I'm not sure I understand the #4 answer.
I thought it was a voltage tripler.... 268 VAC becomes 820 VDC
and as is now has D1 D2 D3 D4 diodes.
Are you saying DROP out D2 and D4 ?

I make the following observation regarding the GREEN circuit.
(1) The circuit is a voltage DOUBLER.
(2) The transformer RMS voltage is 268 volts AC RMS.
The PEAK voltage is 1.41 * 268 volts.
But the circuit is a doubler, so you'll get (approx) 755 volts.
(268 * 1.41 * 2) volts
Remember - there will be a small voltage drop across the diodes.
The transformer is designed to deliver the rated voltage at the rated
current. When the load is light the voltage will be higher.
(3) IF you use two diodes in series (4 diodes in all) add high
value equalizing resistors across both diodes. eg 1.5 or
2.2 Meg (rated at the working voltage).

I would protect each winding with a fuse. Use "safe" fuse-holders - a holder
that does not allow contact with high voltage when the fuse is
replaced/removed.
I would add an indicator to show complete discharge of capacitors - eg neon
+ limiting resistor.
If you want, you can put the filter choke in the negative supply line.
This has the advantage that the choke winding is at a low potential.
If the winding shorts you'll see less damage.

750V must be treated with respect.

Les

Thanks for the input Les.

What is the purpose of th equalizing resistors across diodes?

And

why is there a 6 Henrie choke on the YELLOW circuit but no filter choke
on the GREEN circuit ?

28064. Re: [regenrx] 250 and 750 volt power supply questions #4 2 diodes

Yahoo group: regenrx (2016 — 2017)
Date: 2017-05-10 14:56:26 UTC
From: Jim Scott
Topic: 28059 Message: 28064

Short explanation:

RED goes positive: Current path=D3(D4), C1, RED/YEL | D1(D2) blocking
RED/YEL goes positive: Current path=C2, GND, D1(D2), RED | D3(D4) blocking
Output Current path: C1+C2 to load

Capacitor input power supplies charge to Vp and then discharge during the latter half of the cycle. Ripple comes from the relationship of charge stored in the capacitor, time delay before next charge cycle, and discharge. IN other words, under heavy load there can be excessive ripple.
The choke is used for smoothing the ripple, at the expense of an overall reduction in voltage at the output.

4. could I knock down the GREEN 820V circuit to 750V by adding the BLUE string of 1N4007 diodes?
----The circuit is a voltage doubler, and should develop about 1.41xVsec or about 758VDC, where Vsec is the secondary RMS voltage of the transformer. The circuit will require only a single 1N4007 diode in each leg of the circuit, not two.

If you move D2 and D1 down to the Red/yellow transformer lead with cathode pointing to transformer and then tie the second (D1) diode anode to the cathode of D4 you will have a full wave rectifier (not a bridge). So 268 x 1.414 = 378v and the electrolytics would bump it up a bit more but you are correct, as shown it is a voltage tripler so making it a voltage doubler would give you 536v and the electrolytics would bump it up some.

There is one thing to watch for in these situations. I got bit a few times in the 70's with it.When turning a power supply off you will get a voltage spike and that spike can be 3 times the regular voltage so you can loose a diode string because of it. I did that a couple times. I had a power supply that worked great and one day it failed to come on. I was talking to a Tektronix engineer friend and re told me about the fact that you get a spike when powering down and while it failed to come on it was because the string had popped when I last turned it off but I did not know it til I tried to turn it on again. I used that power supply for quite a while before that happened too!

Does that help or did I just make things more confusing?

Thank you.

Jim

Perhaps this is a really dumb question but I'll ask anyway.
I have a collection of never used transformers I picked up over the years with the intention
of putting into service in tube radios.

Some have markings.... some are mystery meat.
I figured it would be easy enough to some day OHM out the coils and figure out which are pairs and center tapped.

some are marked 400-0-400
some are marked 700 volts.

So here is my question:

Is there a reason to use a voltage doubler circuit on a 300 volt transformer as was done in an original
factory built receiver that uses a 700 volt tube circuit OR is there nothing wrong with using one of
my 700 volt transformers to build that circuit?

Hi,

Been building, repairing and "parting out" radios for 60+ years. "Volts
is Volts". So long as you can get the desired Voltage and current,
AND it is clean, I.E. no ripple or noise riding on it as some switching
supplies have, it should work just fine for you. Of course there are
some ways of getting that Voltage that is more aesthetically pleasing to
the eye, or makes common sense. Yes, you 'could' build a supply that
provides 300 Volta at 20 Amps and power a 1 tube regen receiver
requiring maybe 10mA with it, but it's not very practical.

WHATEVER YOU DO, keep SAFETY foremost in mind, making sure there isn't
any shock hazard to the user or pets or other visitors to the shack,
nor does it create a fire hazard. . .

28070. Power Line Filter - 12v @ Some Ungodly Number of Amps

Yahoo group: regenrx (2016 — 2017)
Date: 2017-05-13 17:20:34 UTC
From: J Ed
Topic: 28070 Message: 28070

I've been thinking of how to solve a problem. This can effect any of us who use direct conversion receivers, which includes regenerative receivers in a way.

If you're not using a switch mode power supply to power your projects (be it a 12v one, or something more exotic), chances are there are such a power supply in the vicinity of your receiver or antenna. They tend to kick out switching noise in all directions, particularly the cheaper ones which might not be designed for low noise.

My intent is to make a seven-pole filter for a DC line, which would block noise coming in from the power lead. My problem is making it for a 30 amp capacity, as my main power supply can put out this much and powers my radio transceiver. The supply of inductors capable of handling 30 amps is not wide and various.

If I were doing this for a QRP transceiver or a receiver, I'd have no problem in making a simple filter. I'm just wondering if anyone has tips on constructing a high-current filter like this. The goal is to make something that blocks noise from power supply cables and the power supply itself, so I get an overall reduction of switching noise in the MF/HF bands of 80 dB or more.

Ed AE7TE

Hi Ed,

My solution to eliminating noise coming in on the power line is the use of batteries. I use then even with tube gear sometimes. Higher powered (100 watts +) might be less practical but mobile radios from a few dozen years ago with tubes produced 100 watts+ with batteries. But that is not in your receiver! I have 100 watt solid state transceiver and it runs full bore with a little less than 20 amps. A car battery runs it for a long time. What are you running?

Hi Ed,

I like to 'overbuild' too. If it is for an AC powered DC supply what
about installing the filter on the AC input side? The current will be
much lower there - certainly less than 5 amps. more like 2 or 3 amps.
Smaller parts will be suitable there.

Hi Bill,

That's a good idea. Such a filter can be salvaged from a dead microwave.

The reasoning for the low side filter is to place a filter box right next to the unit under test, connected with inches of power wire. Even though a 12v DC line is low impedance, the filter will reduce switching noise generated by the supply as well as noise picked up by the wiring.

Some power supplies suppress noise better than others, but I've found that a 30 amp linear DC supply is going to be next to prohibitive to build. Finding a 16v AC, 50 amp transformer is going to be an extreme challenge.

28075. Re: [regenrx] Power Line Filter - 12v @ Some Ungodly Number of Amps

Yahoo group: regenrx (2016 — 2017)
Date: 2017-05-13 19:27:20 UTC
From: Bill Cromwell
Topic: 28070 Message: 28075

Hi Ed,

Look at garage sales for old Automotive battery chargers -some can
exceed 50 amps - for the iron. Most of those also have a high current
ammeter. I have set the iron and the meter from one of those aside for a
"big honking" power supply here.

28076. OT: Need schematic for Samlex RPS1215 PS

Yahoo group: regenrx (2016 — 2017)
Date: 2017-05-13 20:49:46 UTC
From: Phil
Topic: 28076 Message: 28076

Hi,

Looking for a schematic or manual pdf of a Samlex RPS1215 PS.

A ham friend brought one (15-20 Amp PS) to me for repair. Usually I find Power Supplies a fairly easy 'fix', I've probably done hundreds of them.

Anywhoo, this one was blowing fuses and I quickly found that the 10 Amp diodes on the regulator board were shorted. The big honkin' bridge rectifier was good.

I replaced the 100PIV 3Amp axial lead diodes on the board with a pair of similar (but 100PIV 10 Amp) diodes. Put in a new fuse, checked it out and the critter put out a regulated 13.8V like it should.

Put the "load tester" (a modified auto battery load tester) on it and slowly brought the current up. As soon as the current reached 10 Amps (it's rated 15A continuous, 20 Amp peak) the fuse again blew and this time the big honkin' main bridge rectifier was shorted, the two on the board that I replaced were OK. I don't have that bridge rectifier and need to order some.

But I can't just keep stuffin' rectifiers in it, I need to find the REAL reason it's acting up. By the way, this seems to be much more cheaply made than the typical Astron Supply which I'm VERY familiar with.

At this point the owner told me to just part it out as he's bought a new Astron, but I WOULD like to fix it and give it back as a spare if I could.

Problem is, I've done a pretty thorough Google search for a schematic (or other info). Only thing that turned up was some schematics for Samlex products with similar model numbers in the UK, but they ARE NOT the same thing, their usually battery chargers or similar products, nothing the same circuit wise. I just hate to let something as simple as a PS get the better of me . . .

Hi,

Why not put a simple 30 filter in the lead from power supply and then
build into the rig(s) a GOOD filter and put it in the power lead to RX
part of rig. Noise on the power in TX, well not good, will not upset
your listening.

Every 10 dB of noise reduction is a bonus. If I can place a filter on every power line, all the better. Problem will be, if I do all that and it still gets into the antenna because of all the devices in the house and otherwise.

Sometimes I think it would be better to eschew home operating and go portable.

28079. germanium diodes testing 0.26 volts to 0.6 volts

Yahoo group: regenrx (2016 — 2017)
Date: 2017-05-16 16:50:49 UTC
From: Rob
Topic: 28079 Message: 28079

When testing diodes with a simple digital meter with a diode checker function I sort of expect
to see 0.6 volts on a 1N4007 or a 1N4148

and buy germanium diodes for radio receiver circuits..... expecting something more like 0.3 volts.

The Russian diodes have stripes.... with no real pattern of always being on the cathode (-)

http://www.learnmorsecode.com/regen/diodesstripes.jpg
http://www.learnmorsecode.com/regen/diodestripes2.jpg

I thought that the idea that plain silicon diodes like 1N4007 and 1N4148 were not of any use in simple crystal radio circuits because they have that 0.6 voltage drop while the historic ...in every text book crystal radio circuit.. 1N34A was supposed to be half that voltage.

I did a comparison with 8 different cat whisker germanium diodes.
I have one that is a mystery.... no markings... so I just called it BULGARIAN.
My 1N34A diodes consistently tested between 0.38 and 0.4

The BULGARIAN diodes all tested real close to 0.6

While the Russian diodes where 0.32 to 0.38

and the Russian D311 (black beauties) were 0.23

AND
just for giggles I will toss in the modern SCHOTTKY 1N5711 at 0.27

I have used the 1N5711 successfully in the bare bones simple crystal radio...big coil with slider.

http://www.learnmorsecode.com/help/alldiodes.jpg

So it looks like the D311 is the lowest and I assume it would be best for simple crystal radio RF circuits...
but I hear no difference between any of these GERMANIUM diodes....
they all receive AM broadcast radio here.

http://www.learnmorsecode.com/help/D311diode.jpg

From: Hubert Miller
Topic: 28079 Message: 28085

Maybe what you're hearing versus the different low-voltage diodes is due to your output impedance, the headphones. If the headphones are much lower impedance
than the input circuit, the small difference between diodes will not matter much. In a circuit with available gain, not a crystal radio, I don't think this small difference will be even noticeable.
I have not played with crystal set circuits for years, but as I recall, even a small difference between Ge diodes was worth checking out. When you're listening to a station at the absolute low margin of understandability, even a very slight improvement in diode operation is noticeably worthwhile. And I ALWAYS use piezo earpieces or phones
as I find those with their very high dc AND ac resistance to perform much better than mag phones even with a transformer.
Looks like I need to acquire some D311 for my next round of experimenting.

I tried out an idea for a homemade variable cap for a hillbilly crystal radio. I took two beverage cans of the narrower kind. One I cut both end caps out of, leaving me a cylinder. Then I cut it lengthwise so it could slip like a cuff over the other can. You slip it over the other can and then use a couple tabs of tape over the split in the outer can, the "cuff", to hold it together snugly over the central, uncut can. This cuff then slides over the intact can. I didn't yet devise a way to apply contacts to the cans but I think very small screws and light wire will do. My effort so far was only 'proof of concept'. For the sliding "cuff" I found a semicircle of Styrofoam at a crafts store, very light, that I can glue to the end of the 'cuff' part to minimize hand capacitance effect.

Neat photos, thanks. I don't quite understand and couldn't see how the crystal is held, but I'll think about this and maybe look for the part. I do have a hunk of raw galena to put to use.
One of my earlier "slide capacitors" measured 700 pF max.
This gave me a silly idea to make a longer "trombone" or "slide capacitor" and at max capacity, charge it with some yet to be decided voltage, then quickly pull it to its minimum capacity position and have it flash a neon or fluorescent lamp. Q=CE.
-Hue

>Hue,
Here is another idea for a tuning capacitor made from household materials - a cake pan cut in half. One half nests inside the other. It turned out to be 180pF. For a detector I used a chunk of raw iron pyrite held in a kitchen cabinet door catch with a curtain hook for a cat's whisker. Works great for local AM stations as most xtal sets do. Mike, W6MAB888

The classic approach to this is to add a little forward bias to the diode. I have a bias control on my crystal radio so that I can set the bias for optimum operation.

Voltage-multiplying detectors sound attractive on paper, but in the end,
they are just impedance transformers (and poor ones at that). In most
cases, far better results would be obtained by preceding a single
detector by a good impedance matching network instead.

This is ALL I have every used for crystal radios since the 1960s. However I find you must use very high impedance headphones with it, and I mean impedance with
a high DC resistance component also. I mean piezo phones, the little single units or Brush (company) headphones from the past.
I have tried a fullwave 4-diode bridge. This is not worthwhile because the back capacitance of the nonconducting diodes seems to load the tuned circuit, with
consequent degrading of selectivity.
I have not tried a voltage quadrupler, but my guess is, it is not workable. The fullwave voltage doubler simply makes use of both half cycles. You can't get more
energy from the circuit than is there. I have seen published circuits showing a 2-diode fullwave detector with either a tapped single coil or 2 tuned circuits and
I'd guess the results are like the fullwave voltage doubler, the tapped coil is more complicated, but this does allow a better match, maybe, to a load with less than
very high impedance.
At one time, 1970s, I tried a voltage doubler using two high-beta Ge transistors with the bases driven from coupling coils of opposite phase from the collector
current. That seemed to have promise and from time to time I think about trying that again, but so far not. I think it's real interesting working with extremely
low current circuits. One of my old original transistor projects book has an oscillator circuit, I don't remember the exact numbers but at audio freqs I think the
thing generated an audio signal down to something like 8 uA current. I suppose this is kind of a silly pursuit, like seeing how low a plate voltage you can use and
still maintain oscillation.

Hi Arnie,
this VOLTAGE QUADRUPLER detector published by the GQRP Club
SPRAT magazine .... is a unicorn????
I can't find it.

Could somebody PLEASE post a JPG picture of this circuit?

Rob

Nearly any example should work. google your way to WBR regen receiver, there is a ham in Norway that has a schematic with a npn preamp. Email me diect if you cant find it.

Lee, instead of quoting Mr. Tongue saying the circuit is of no value, why not try this:
Lash up a simple crystal circuit: tuned circuit, diode, piezo earphone, with filter cap and/or resistor as you like.
Then convert it to a fullwave voltage doubler.
Note the difference in reception of the weakest signal you can make out, at the very margin of understandability.
Then report your results back here.

Topic: 28079 Message: 28106

Mr. Tongue is /absolutely correct/, and I have already given the reason. I'll explain it again with a bit more color.

A voltage doubler doesn't magically create energy, so if an increase in voltage is obtained (and this is by no means guaranteed), it must come at the expense of a decrease in current because there is no source of additional energy beyond what is in the received signal. An increase in V, accompanied by a decrease in I, implies an impedance increase. That's all.

For every source impedance, there is one (and only one) load impedance into which power delivery is maximized. That impedance is the complex conjugate of the source. That means equal resistances, and reactances that are algebraic inverses. By definition, if you already have matched impedances, you are doing the best that one can do, so adding a voltage doubler in that case can only worsen things. It's only in the case where your source impedance is too low that an upward impedance transformation, such as that possibly provided by a doubler, might improve things. If a doubler helps, it's a definite sign that the original configuration was very far from optimally designed. Far better performance would be obtained by throwing away the doubler, and providing a proper match.

It's important to understand that a diode is a very inefficient impedance transformation element, and it gets more so as signal power drops. If you are seeking to improve performance, the best approach is to use an actual impedance matching network, rather than a diode-based circuit that provides an impedance transformation as an inefficient side effect. Low-loss matching will always outperform voltage "doublers".

Tom,

Thanks for explaining this to the group. The bottom line as you mention is, "There is no free lunch." I have a good friend really into crystal sets. I mean really into them. He is also an electrical engineer. He will spend $1000 building one. He is a serious crystal set guy. He has logged in way over 150 stations with his sets. What is important to him is: 1. Sound powered headphones, 2. matched antenna impedance and audio impedance to headset (Audio Impedance transformer), 3. use of a hand picked holly grail diode, 4. 660/40 Litz wire coils air wound, 5. Selectivity links, 6. Ceramic insulated silver plated variable capacitors with excellent grounding tabs, 7. All parts mounted with ceramic standoff insulators, 8. Gear reduction tuning capacitor drives. Plus a good antenna. I've had the privilege of listening to one of them. All I can say is WOW! I never knew a crystal set could perform like this.

Topic: 28079 Message: 28109

I believe the DX logs of high-end crystal radios is mostly attributable to the improved selectivity of high-end designs. In the old days, using even super basic crystal radios, considered inefficient toys now, people were hearing stations 1000 miles away - this was when there were fewer stations on the air to jam your DX station. The old shipboard crystal receivers used to get 1500+ miles distance.
That 660 Litz from China amazes me. I can't see that there's an industrial purchaser for this high-end product and I guess it's a "boutique product" to satisfy a particular narrow market willing to pay boutique specialty prices.

One thing about matching impedance that really surprised me, when I was experimenting with crystal circuits: I found that I could still hear a local or two with the headphones 32 ohms type. That is one substantial mismatch; you'd almost think, this should not work! I suppose it's the sensitivity of hearing plus the good level of the local signal put it into the ear's low end hearing range.
I think I concluded after trying a few audio matching transformers, yes, an impedance match is important, but not as all-important as you think, and the power output delivered does not fall off as rapidly as you'd think. In other words, nor is a perfect impedance match a free lunch.
-Hue

28110. RE: [regenrx] Re: germanium diodes testing 0.26 volts to 0.6 volts

Topic: 28079 Message: 28110

Because of the performance of the diode, you want to operate it at as high a voltage as possible for the input power - so this means, yes, high impedances in and out of the diode. The highest input, diode driving impedance we can get is the parallel tuned circuit with low - C. Then if you have a very high impedance load, around 100k with some piezo phones, you do have a mismatch, but not a gross mismatch as the usual old-time circuit with something like 2k - 14k ohm magnetic headphone. This is the circuit, a very basic circuit, I am talking about. If you add one diode and a 1 nF cap to this circuit, you have a fullwave voltage doubler and you absolutely will notice the increased output.
I am NOT talking about a magnetic headphone passive receiver with a high-low matching audio transformer. I am not talking about a free lunch or magic energy. It's just a simple kink to improve the most basic crystal set circuit with just a couple parts, to derive power from the other half of the RF cycle. Some different considerations apply to the case where the output device (headphones) are very high impedance. In this case, you do not even need a DC circuit after the diode - you can even have a capacitor in series, the "floating diode"
circuit that some people say "can not work." This is a simple real-life experiment with real-life off-the-shelf parts. If you disagree, and I show you the parts you have to work with,
how do you arrange them for a better impedance match?

Hi Lee,

It sounds like your friend has built the ultimate crystal radio! I've done less than half of those things (sound-powered phones are miraculous for xtal sets), but it's always been on my to-do list to go further. It really is amazing how much performance one can squeeze out of a completely passive receiver. Of course, we must also give the human auditory system its due -- our ears can detect signals so feeble that they displace the eardrum by less than the diameter of the hydrogen atom!

--Cheers,
Tom

Hi Hue,

Please read what I took the trouble to write in detail.

Summary: If you notice improvement with a doubler, it's a sign that your original circuit was horribly mismatched. It is not a sign that the doubler is "good". Throw away the doubler and add impedance transformation as necessary. No extra diodes, which are terribly lossy. The receiver will perform much better than with the doubler.

You need to perform fair comparisons. Simply noting that the doubler improves performance in a limited circumstance tells you almost nothing about what is actually going on.

--Cheers,
Tom

My friend also is particular what audio impedance transformer he uses. Some are more efficient then others. I can't remember the number, but he loves one made by UTC. I think the secondary is around 1000,000 to match the sound powered headphones. (Sound powered headphones use both halves of the wave for driving the earpiece.) His whole goal is to remove as much loss as possible everywhere. The combination of all the small savings adds up to a significant improvement. When you listen to a crystal set like this you would swear you are listening to a device using many transistors and or ICs. I never thought it possible to have something like this work this well with no power supply. I am sure at $1000 to build a set like this, he is on a curve that is leveling out with ever diminishing returns.

Tom, given the circuit components I described, arranged in a simple crystal set, how do you achieve improved impedance matching? As I said, this is a simple kink to improve (an existing) basic set. I am not going for the ultimate in effort that Lee described, I am talking off the shelf, Radio Shack (once upon a time) parts. I'm not missing your point.

I happen to prefer Brush piezo phones, even tho others claim the soundpowered are better. When I test the piezos, I do it by just touching the leads together, or touching one lead to a key or tool or something metal, which you can hear. Also with these, you can hear the 10 kHz beat note indicating a weak signal, maybe too weak for audio.
(or at least I could hear 10 kHz, when I was younger.)

Subject: Re: [regenrx] Re: germanium diodes testing 0.26 volts to 0.6 volts

Mr. Tongue is absolutely correct, and I have already given the reason. I'll explain it again with a bit more color.

A voltage doubler doesn't magically create energy, so if an increase in voltage is obtained (and this is by no means guaranteed), it must come at the expense of a decrease in current because there is no source of additional energy beyond what is in the received signal. An increase in V, accompanied by a decrease in I, implies an impedance increase. That's all.

For every source impedance, there is one (and only one) load impedance into which power delivery is maximized. That impedance is the complex conjugate of the source. That means equal resistances, and reactances that are algebraic inverses. By definition, if you already have matched impedances, you are doing the best that one can do, so adding a voltage doubler in that case can only worsen things. It's only in the case where your source impedance is too low that an upward impedance transformation, such as that possibly provided by a doubler, might improve things. If a doubler helps, it's a definite sign that the original configuration was very far from optimally designed. Far better performance would be obtained by throwing away the doubler, and providing a proper match.

It's important to understand that a diode is a very inefficient impedance transformation element, and it gets more so as signal power drops. If you are seeking to improve performance, the best approach is to use an actual impedance matching network, rather than a diode-based circuit that provides an impedance transformation as an inefficient side effect. Low-loss matching will always outperform voltage "doublers".

Hi Hue,

One way to provide an impedance conversion at the input side is to connect the antenna to a tap on the tank, and then to drive your diode detector with another tap. To effect an upward transformation, the antenna connects to the tap closer to ground, and the diode connects to the tap closer to the top of the tank. If the tank has any kind of reasonable Q, it will perform the transformation with much higher efficiency than a doubler would. You will present a higher voltage to your diode detector (and deliver more to your load) than if a doubler were used.

I'm recalling now that I did some tries with audio matching transformers a couple years back. Even with the high impedance headphones, I thought
I'd try impedance transformation ratios in the 2:1 to 3:1 range to better match the input. The tuned circuit was a series resonant high-inductance
with the diode on the inductance element. I had found some carbon microphone transformers and some 400 Hz power transformers I had pulled
out of old test equipment, these had a variety of taps. I basically found, no improvement to be had. I attribute this to: still less than ideal match found
with my particular transformers, and 2, it's not that all that critical for impedance values that are "in the ballpark". I'm not totally satisfied with results
from those tests, and I'm going to have to gather a bunch of my transformers and have a rematch. I was using the various high voltage windings of the
400 Hz power transformers for the various transformer ratios. I found those power transformers were worth keeping as the inductances even just for
audio choke use, could be wired to give 35-50 H.

Tom, my conditions are a short, capacitive-reactive antenna. Tapping down the coil is counterproductive for this case. With the antenna and the headphone I use, tapping down either antenna
or diode tap results in diminished output (with improved selectivity as result of decreased load.) There is a good reason I maximized the inductance in the tuned circuit.

Subject: Re: [regenrx] Re: germanium diodes testing 0.26 volts to 0.6 volts

Mr. Tongue is absolutely correct, and I have already given the reason. I'll explain it again with a bit more color.

A voltage doubler doesn't magically create energy, so if an increase in voltage is obtained (and this is by no means guaranteed), it must come at the expense of a decrease in current because there is no source of additional energy beyond what is in the received signal. An increase in V, accompanied by a decrease in I, implies an impedance increase. That's all.

For every source impedance, there is one (and only one) load impedance into which power delivery is maximized. That impedance is the complex conjugate of the source. That means equal resistances, and reactances that are algebraic inverses. By definition, if you already have matched impedances, you are doing the best that one can do, so adding a voltage doubler in that case can only worsen things. It's only in the case where your source impedance is too low that an upward impedance transformation, such as that possibly provided by a doubler, might improve things. If a doubler helps, it's a definite sign that the original configuration was very far from optimally designed. Far better performance would be obtained by throwing away the doubler, and providing a proper match.

It's important to understand that a diode is a very inefficient impedance transformation element, and it gets more so as signal power drops. If you are seeking to improve performance, the best approach is to use an actual impedance matching network, rather than a diode-based circuit that provides an impedance transformation as an inefficient side effect. Low-loss matching will always outperform voltage "doublers".

This has been my experience. I understand the use of the super-Litz wire, and I'll probably buy some, but I'm a believer in ferrite cores, as this minimizes the wire used, and that's a benefit. In my more recent very basic experiments, I used one of those N-in-one kits with the spring clips. At these frequencies tho you can just lay the parts on your table and use alligator test leads to connect everything. I used two ferrite core coils in series, selectable one or two, and I loosened the cores so I could adjust the inductance more. As my usual antennas are short, high capacitive reactive, I wanted inductance in series to resonate with this capacitance. So basically I used the series resonant input circuit, also used in the Heathkit CR-1 and the emergency crystal receiver in the WW2 Mackay ship radio console, among others. Another way to do this is with a tapped coil, to tap near the top of the coil, or as many experimenters do, just connect right to the top of the tuned circuit via another variable. Tapping down the coil only applies if you have something like a long antenna. I also found that impedance matching of course, worthwhile but do not expect a sudden peak in performance, it's not a sharply defined boost like tuned circuit resonance. I am aware the voltage doubler doesn't work and I shouldn't use it, but I say, why not lash up some simple single-tuned circuit, with some provision for antenna matching, and then add the two components and try it? It takes about a half hour at most and the readers can prove or disprove this for themselves.
I was curious last night and looked at a couple Brush piezo phones with my basic test equipment. One pair seemed to be defective, the other set measured 2M ohms DC and 700 pF. That's very preliminary and at present I don't have an audio generator so I could do a more informative test.

Subject: Re: [regenrx] Re: germanium diodes testing 0.26 volts to 0.6 volts

I built two crystal sets, one with air-core coils and one with ferrite-core coils, and both based on a circuit in the "Ask Me Another" column in the Oct-Nov 1967 issue of Radio-TV Experimenter. As published, the circuit has two 1N34 diodes in a voltage doubler configuration. I also tried both sets in the traditional single diode configuration. Their were no differences in volume or selectivity with regular 2000 Ohm phones, but both volume and selectivity were improved with the voltage doubler configuration when I used my Mil Surplus 17,000 Ohm phones. I attribute this to better impedance matching and some unloading of the tuned circuit with the doubler. Also, the performance of the set with ferrite-core coils was slightly better than the one with air-core coils. Pictures of circuit and sets available as attachments to off-list email request. Uploading to yahoo is too much bother, and besides, this is off-topic for regenrx. Mike, W6MAB

Theory is fine, but it's not the "end-all" to explain why some things
work, and other things don't work. Try a circuit and see for yourself
whether it works or not.

Way back in 1960, Popular Electronics published a voltage doubler
crystal receiver that would drive a loudspeaker. I built this crystal
set exactly as described back in 1960. This little receiver performed
very well. Although the volume wasn't room-filling, it was plenty loud
enough for night time listening. I placed the receiver on the headboard
of my bed and was lulled to sleep by music every night. I don't remember
much about the antenna, except it was a long wire end-fed (probably
about 20 or 30 feet long because the area where I lived at the time was
small. It does feature a dual-tuned input - which may explain it. I
didn't play around with it and remove one of the diodes and see if it no
longer worked. I was just happy that it served my purpose. I wish I
still had it, but I was in the Air Force back then and through many
moves during my career it was lost.

Theory is, in fact, the end-all to explain things in electrical engineering. Experiment is of course the final arbiter of /whether or not/ something works, but the explanation of *why *it works (or doesn't) is theory. Physical intuition is helpful in inventing, but it only gets you so far. Without theory there's no way of knowing how much better your circuit could perform. Without theory, you're left only with unreliable lore, less reliable superstition, and almost wholly unreliable opinion. Some people prefer that to actual science, and that's fine, but if one is serious about understanding what they're doing, then theory it must be.

Electrical engineering is extremely well understood. It would not be possible to construct multibillion-transistor GPUs and terabit/s millimeter-wave circuits were it not so. One does not design a cell phone -- which must successfully resolve 10 femtowatt signals in contested environments -- without careful adherence to theory.

This circuit could use an optimized input circuit. The one-size-fits-all input coil is not the best way to maximize signal.
The most tuned circuits I used was three in cascade; this was many years ago when living north of Seattle, I wanted to pick up a 1 kW classical music
station in Seattle, KXA. Now both the format and this station are gone. The downfall of my basic crystal set is the single tuned circuit. It does a very
good job extracting maximum power from the antenna, but this loads the tuned circuit, and a second tuned circuit is really called for.
The farthest I have heard with such a simple set and makeshift antenna is about 900 miles. But it needs more selectivity because strong locals cover
too much.
I read that coil experimenters had gotten Q figures up over 1000. I would like to try that too, but that will have to wait. I do have some commercially
made ferrite core antenna coils with Q=450 and maybe this will find its way into a crystal set project.

From: Hubert Miller
Topic: 28123 Message: 28123

I want to check an assumption of mine. "Single bearing variable capacitors are not suitable for VFO use". Is this true, that these have
inherent mechanical instability that makes them unsuitable for VFO tuning, and therefore also regen receivers? If so - is a similar
level of stability quality required for such a cap used in the regen control?

I recovered 20 air variables 15-250 pF from boat radio antenna coupler I disassembled. They are in new condition and look good but
they are of the single-hole panel mounting type.

From: Rob
Topic: 28079 Message: 28125

I find all of the detail discussion about double diode...litz wire.....etc ... completely fascinating.
Not to dissuade any purists from building crystal radios here.....
but
my path of experimentation started with crystal radios.... simple minimalist 1N34A radios
to have kids ...scouts and newbies.... get a good induction into the hobby of electronics
and ham radio .... using the bare minimum of parts required to achieve success....to HERE the world on something they built from scratch.

http://www.learnmorsecode.com/help/xtal1.html

I moved on to the simple bare minimalist regenerative receiver because the crystal radio had very
unpredictable results...good and very bad.
http://www.learnmorsecode.com/regen/00regen.html
And ....again with the same goal..... fast path for newbies.... with dirt cheat readily available components.
The fact that this $4.00 radio hears Cuba.... 1,300 miles away from here pretty much says it all.

So when I tripped onto the germanium diode requirement for the regen I needed to find
cheaper diodes.... 5 to ten cents each..... instead of getting mugged for 1N34A prices.
Its all been very educational ... and cheap enough... to buy 1,000 Russian diodes.
I'll never buy another germanium diode again.

Topic: 28079 Message: 28127

I like the idea of "found parts" demonstrating some electrical and electronics principle. It's both silly and beautiful at the same time.
The "found" parts have the desired trash look, but, hey, they are really doing something.
For a "foxhole radio" with the blade detector, for the detector probe I used a pencil, sharpened down to a ridiculous shortness, just point and eraser.
The point was sharpened to maximum sharpness. I inserted a pin just before the eraser holder, to contact the 'carbon' core and thus the
point, to this was connected a thin wire. A stiff wire wrapped around the eraser part held the pencil and permitted adjusting its position
on the blade. It looked wonderful. Visuals, I think, are worthwhile.

It occurred to me on our homemade tuning caps, be they pie-plate or beer can style, one could trim the variable section (rotor) shape
to give a "straight line" tuning rate, via the geometry of the rotor section. Now wouldn't that be an interesting math problem?

Rob, I recall eons ago, when was a young fellow and (more) ignorant, going to a radio-TV repair shop and buying ONE diode for a crystal radio.
The price was something like $2 in 1963 ! I learned from that, how NOT to buy parts!
I started implanting the voltage doubler into existing crystal radios.

One thing kind of on my think-about list: using one of those zinc-plate homemade negative resistance devices to build a total homebrew radio
with actual gain, regeneration in fact, with distance range. My conclusion on how to control regeneration, similar to tunnel diode operation,
is that control via bias level is just too critical, and hence some absorption scheme like Don's slug-absorb circuit would be the best way to control
the regeneration. One could even build the headphone from scratch, if you want to go really gung-ho. This gizmo would really amaze your students,
when they look at the circuit board and see 100% "found" parts.

Hi Hue,

I don't fully comprehend the constraints you've imposed on the problem/solution, but in the abstract, a short, capacitive antenna's impedance can be well matched by absorbing that capacitance into a tapped capacitance divider in parallel with the tank inductor.

Because the radiation resistance of a short antenna diminishes as the square of the normalized length, inattention to loss mechanisms can easily result in the radiation resistance becoming irrelevant. But if one is seeking the best performance, assiduous attention to minimizing loss is essential.

--Cheers,
Tom

Not that my findings are definitive, but I did not honestly get improvement with 'halfwave voltage doubler' (is this also called "charge pump" ?)
I always use the fullwave voltage doubler, the circuit where both output leads are ungrounded. It could be that my series capacitor was less than
optimum value.

Tom, you're preaching to the choir. I taught electronic theory, installation and maintenance of radio and computers for a little over 40 years. I developed a deep interest in electronics when I was in the third grade (I remember the exact moment the curiosity struck me). I'm a believer in theory; however, I do recall that it is theoretically impossible for a bumble bee to fly.

Theory is just our way of trying to make sense, and explain, what Mother Nature does; however, she has thrown a lot of theory in file 13 in the past. The impossible has become possible. With all our knowledge we still know very little of how things really function. da Vinci, Tesla and Einstein were hero's of mine. All were great theorist.

When things work and our theory proves to us that they can't possibly work then there's something wrong with our theory. Actuality trumps theory every single time. And, guess what, we change our theory to fit the actuality. Hi hi.

28134. Bad Heath-Kit DX-20 Power Transformer For Autopsy

Yahoo group: regenrx (2016 — 2017)
Date: 2017-05-18 17:01:23 UTC
From: Sam Neal
Topic: 28134 Message: 28134

Hello,

About a week or so ago someone posted a note asking for a bad power transformer for a DX-20, apparently to check the turns ratio of the windings. I apparently deleted that e-mail.

I have one for you. I have let a lot of the smoke out of it, but there is probably plenty more left.

Say the word and it will appear at your QTH, free of charge.

73,

I wonder if anyone here has used the Radio Shack "Globe Patrol" radio. I just batteried up one I bought at a swap.
I am kind of underimpressed. I don't know if it always worked like this or some parts have degraded or changed value.
I find the regen control the opposite of smooth; I'd call it "abrupt", the fiddly way that gave regenerative radios a bad
name in their later kit years. It also seems to have quite a bit of sensitivity to hand capacitance on tuning. I will have
another go at it after dark; not much on now. Of course at this price level there was no reduction gearing on the main
tune or bandspread controls, so probably much of my unhappiness comes from comparing it to tuning an ex-military
regen set. This example seems to very neatly built, but I note the main tuning is a poly type, low Q, and the bandspread
cap looks really low quality, very chintzy.

Maybe later I'll have a look at the schematic and see if there's room for improvement, at least in the critical
regenerative RF stage. Should be at least possible to improve that gain action in the regen stage.
-Hue

28139. Bumblebees, theory and practice.

Yahoo group: regenrx (2016 — 2017)
Date: 2017-05-19 09:56:36 UTC
From: les.au49@...
Topic: 28139 Message: 28139

Tom Lee wrote a concise posting about the importance of matching the impedance of a load to the impedance of the source, and the value of understanding why this is so.

AC circuit theory is a well-understood topic in basic physics, and the idea that there may be some flaw in our understanding of this topic, or the mathematics surrounding the theory is ... well .... amusing.

For anyone who would like to refer to bumble-bees as an example of how practice trumps theory I provide this link:

http://www.abc.net.au/science/articles/2014/07/29/4056181.htm
http://www.abc.net.au/science/articles/2014/07/29/4056181.htm

Please read the link carefully before dumping more on this topic.

The history of scientific thought has a number of examples of HYPOTHESES that were once popular, but were discarded; there are a number of THEORIES that are better understood today than the time they were first stated BUT I doubt whether "better understood" amounts to "overturning". A most instructive example would be the "overturning" of Newton's Theory of Universal Gravitation by Einstein. Many scientists have "had a go" at Newton's theories, including Richard Feynman. My point here is that a hypothesis is NOT a theory, and I know of no THEORY in science that has been discarded.

Then in 1905 and again in the year 1915 (I believe) Einstein provided a greater insight. It's possible we may, someday, get a better understanding of AC circuit theory, in the same way that Einstein gave greater understanding of Newton BUT I doubt that understanding can ever overturn "theory". As for voltage doubling detectors in crystal sets and impedance matching - I urge you to consider Tom's instructive argument carefully!

I feel a little embarrassed in defending Tom's argument. After all, he knows a good deal more on this topic than I do.

Again, I feel embarrassed because the idea of pointing to the advantage of understanding basic AC theory should not be necessary in this group.

To conclude: Tom has presented a concise explanation for why a voltage doubling detector has no advantage over a circuit that correctly matches the source impedance (here the aerial) to the load (the detector/headphones). Thimk deaply on this poynt!

Les Smith.

PS "Go" Tom!! "Go" maths! "Go" the law of conservation of energy. (This is the basis of the rule about impedance matching.) Now I sit back and watch the flames roll in!! Life is fun!!

There is no difference between theory and practice, in theory. In practice, there is.

No one is saying bees shouldn't fly, or can't fly, or they don't have fun doing it.
I don't care what others may or may not have said to deprecate physics here.
I suggested for a simple crystal radio, or as an addition to an existing simple crystal radio, even commercial product ones,
you could add a couple parts and yes, actually experience a boost in volume. It is true that attention to antenna matching
and output matching boost volume. Everyone knows you want as high impedance phones as you can find, barring an output
matching transformer. As for antenna matching, yes, but you know what, it is NOT a precise adjustment for our receiving
purpose and less than perfect will actually not radically affect your result. In my trials with the circuit, I did use an L network,
or the equivalent of a pi- net if you consider the (relatively small) capacitance of the antenna. This is a tried & true circuit
from many years ago, as I gave examples. Combine this with a full-wave rectifier and you extract more energy from the
wave than with an even more minimal part count. I am not talking about perpetual motion, free universal energy magic.
If you don't believe me or don't want to believe me, or others who have built the circuit, I invite you, again, to actually lash
it up on your desk. It's not really that hard, is it?

28145. Uses single-bearing variable caps

Yahoo group: regenrx (2016 — 2017)
Date: 2017-05-19 19:41:26 UTC
From: Hubert Miller
Topic: 28145 Message: 28145

I was last night looking at the ARRL pub "How To Become a Radio Amateur", 1953, this is the early one with the single-valve receiver
and single-valve "slatboard" transmitter, and in the photo I note the bandspread, main tune, and regen controls are all single bearing
variables, so I conclude, at least for "beginner quality" function, these parts are adequate. The text explains that altho the receiver is
bare-bones minimum, it actually does function to communicate over distance. The article is for ARRL work, disappointingly
not so well proofread. The receiver project includes 2 coils but does not actually state the frequency range of the second coil except
that it tunes 40 and 20 meter bands. The grid resistor is stated as 15M but I suspect this is possibly a misprint and they intended 1.5M;
a resistor in the two-digits megohm range is what I have often seen in valve superregen circuits, as the high value grid resistor with
lots of feedback causes periodic blocking of tube conduction - which is superregen function. I would like to build this receiver and
experience just how well such a simple device works out for long distance coverage, but I can't bite on another project now. The
receiver calls for a 5 x 7 x 2 inch chassis and 6 x 7 inch front panel piece. Maybe I'll start at least looking for this metal, to start with,
or have one of you who are capable, make such for me.
The transmitter section of the article states that it covers 80, 40 meters with 2 coils, but there is no detail on how to make the second
coil. Not that big a deal, but for an absolute beginner these errors didn't help.

Since I found myself with an abundance of single-bearing 15-250 pF variables, and the ARRL project in the '53 book
calls for 100 pF, I decided to try the old kink of pulling rotor plates off a sacrifice capacitor. I found with care this is
very do-able. This is a less desirable option than using the original spec part, as when you're done, you have unused
unnecessary stator (fixed) capacitor plates out there in the breeze being sensitive to temperature variations, but it
is a workable option. I'm wondering if I can get down to a capacitance number for the bandspread capacitor role;
I'm going to try for it.

All -

It never ceases to amaze me how many experimenters manage to forget the idea of using a series fixed capacitor to make a larger capacitor, either fixed or variable, smaller (electrically). The advantage is of course that the original variable capacitor is not physically damaged by doing this, and can be used in another design if the first does not work out for some reason. The value of the needed series cap can be determined by trial and error, or more precisely by resorting to some basic math. Why permanently damage an increasingly rare part for the sake of expediency? Just my 2-cents worth.

I would agree with your note if in the next to last sentence you said "increasingly rare existing radio" .
The part I am working with is not a full-frame high quality sought-after capacitor. It does not have the fiber stator plate connecting
piece between flimsy plates some BC type radio variables have. This piece is pretty robustly built and I detected that removing plates
does not weaken it like what happens with many capacitors. I have seen articles on decreasing the tuning range of some radios
by inserting series capacitors in each gang; I agree that's the only way to do this, if you want to achieve that.
Also, getting down to 20 pF for a bandspread capacitor by inserting a series capacitor to a 250 pF variable strikes me as kind of
silly. I am not sure removing plates from this 250 pF down to 20 pF is practical either; it won't have a very good max/min range,
but I'm going to see. I can sacrifice one to see how practical or impractical this is.
Unlike with full-frame variables, the plates in this
single bearing trimmer type capacitor are easy to access.
I agree that if you have a good quality "real" variable capacitor, don't hack it.

The single-bearing caps I have are screwdriver adjust with locking collar. I had asked about how to extend the very short exposed
tuning shaft. The way these caps work is this. There is the threaded shaft bushing where the nut holds the capacitor to the panel.
To the front of this bushing is a narrower diameter bushing which tapers down to the front and also is split longitudinally in 3 cuts to
its length. Thus the locking collar nut as it is threaded on tightens this bushing against the tuning shaft preventing rotation. I found
that I can saw around this front bushing and as I do so, its three parts (or tines or prongs) just fall off. This does not damage the
mounting threads to the rear of this collar. This leaves an exposed shaft of 5/16 inch which is enough for many of the smaller knobs.
Or more to grip onto for a shaft coupler. "The price was right" on these. The coupler also had two high quality airdux type coils and
a score of high voltage fixed RF capacitors.

I thought I'd better fine-tune my previous note, remembering my little experiments.
YES, antenna matching is very important! I have never been a fan of the circuits that use a "one size fits all" type input, I mean something like a fixed
input coil. That is leaving precious picowatts on the table. I DID find that attention to better antenna matching, for maximum current from the antenna,
gives a big boost to volume, and so it's essential. The series circuit used in the Heathkit CR-1 and some others does this practically and effectively. I have
not invested again in soundpowered phones after having a bad experience with defective ones, defective not unexpected after so many years. I just like
the piezo phones for their very high impedance with lower cost and complication, and I like their tonal response – some people don't. And as I said, when
I can hear it in the headphone when I just touch the leads together, that impresses me. I am suggesting anyone interested try the voltage doubler as an
addition to this simple circuit, I mean matching-tuning input circuit, High impedance phones, and see if it's worthwhile.

Hi

I have been following these messages with great interest for use of various types of Detectors for my Sr Citizens SWL/Scanner Club's project of building some Steampunk Crystal Radios using a combination of Antique/Vintage components with Modern components & circuitry. To come up with an Object de Arte as well as a highly functional Radio.

The basic detectors will be a Cats Whisker and a high quality 1N34A; as well as a set of banana jacks to allow moving to other LEVELS both Up, Schotkky , MOSFET and Infinite Impedance circuit boards & Down, Foxhole Razor, Blade. Rusty Nail etc. etc...

We are looking for comment/advice both anecdotal and theoretical, Now off to a little off topic off topic, We have a couple of Antique TRF 3 RF Stages Radios (Atwater Kent Model 2 C 4640 Big Box) that we want to convert to lower voltage, Solid State or Hollow State. We are exploring the Idea of using Radios on a Chip and Simple Radio PCB's as RF amplifiers. Essentially not bleeding off the RF to ground at the Detector and directing RF to the next stage.

Now to put the Fox in the Chicken House or more aptly the Bee Hive.
Them's that can, do, them's that can't, teach.
Technicians are hands on at the bench, Engineers theorize at the desk

When testing diodes with a simple digital meter with a diode checker function I sort of expect
to see 0.6 volts on a 1N4007 or a 1N4148

and buy germanium diodes for radio receiver circuits..... expecting something more like 0.3 volts.

The Russian diodes have stripes.... with no real pattern of always being on the cathode (-)

http://www.learnmorsecode.com/regen/diodesstripes.jpg
http://www.learnmorsecode.com/regen/diodesstripes.jpg
http://www.learnmorsecode.com/regen/diodestripes2.jpg
http://www.learnmorsecode.com/regen/diodestripes2.jpg

I thought that the idea that plain silicon diodes like 1N4007 and 1N4148 were not of any use in simple crystal radio circuits because they have that 0.6 voltage drop while the historic ...in every text book crystal radio circuit.. 1N34A was supposed to be half that voltage.

I did a comparison with 8 different cat whisker germanium diodes.
I have one that is a mystery.... no markings... so I just called it BULGARIAN.
My 1N34A diodes consistently tested between 0.38 and 0.4

The BULGARIAN diodes all tested real close to 0.6

While the Russian diodes where 0.32 to 0.38

and the Russian D311 (black beauties) were 0.23

AND
just for giggles I will toss in the modern SCHOTTKY 1N5711 at 0.27

I have used the 1N5711 successfully in the bare bones simple crystal radio...big coil with slider.

http://www.learnmorsecode.com/help/alldiodes.jpg
http://www.learnmorsecode.com/help/alldiodes.jpg

So it looks like the D311 is the lowest and I assume it would be best for simple crystal radio RF circuits...
but I hear no difference between any of these GERMANIUM diodes.... they all receive AM broadcast radio here.

From: Hubert Miller
Topic: 28154 Message: 28154

Pulling 12 rotor plates from this variable capacitor, I finished with a range of 7-90 pF. I overshot a little, as with one more plate left on,
it was 105 pF. I am pretty happy with the result. I converted a screwdriver adjust, minimally useful component to useful
component for a minimal receiver.

Here's what I think about your question. If you get a strong enough signal to light LEDs, I say WOW! You either have a hellacious large antenna and/or are quite close to a broadcast station. Also your LEDs will not work at any level signal but extremely strong.

As for the current meter, you want to find a 50 uA meter or better. A large meter face is nice. Good luck! I found a few 30 uA large meters which I tweaked down to about 25 uA. Trying to remember, but I seem to recall 10 uA meant – in my situation – a readable signal. This is for pretty low level signals. If meter pegs on strong signals, have a toggle switch to switch in a parallel resistor to increase the range.
The series microamp meter will only work with magnetic headphone circuit. It will not register any current with piezo or ceramic headphones.

Subject: Re: [regenrx] Re: germanium diodes testing 0.26 volts to 0.6 volts

OOPS.....
I left out a sub topic.
The use of Diodes in parallel including LED's to get some visuals on strong signals.
Also using a microamp meter to get some hard data.

"Urban Legend" was the phrase I was looking for in my Bee Hive message.

Hi

Thanx

Hi

I have been following these messages with great interest for use of various types of Detectors for my Sr Citizens SWL/Scanner Club's project of building some Steampunk Crystal Radios using a combination of Antique/Vintage components with Modern components & circuitry. To come up with an Object de Arte as well as a highly functional Radio.

The basic detectors will be a Cats Whisker and a high quality 1N34A; as well as a set of banana jacks to allow moving to other LEVELS both Up, Schotkky , MOSFET and Infinite Impedance circuit boards & Down, Foxhole Razor, Blade. Rusty Nail etc. etc...

We are looking for comment/advice both anecdotal and theoretical, Now off to a little off topic off topic, We have a couple of Antique TRF 3 RF Stages Radios (Atwater Kent Model 2 C 4640 Big Box) that we want to convert to lower voltage, Solid State or Hollow State. We are exploring the Idea of using Radios on a Chip and Simple Radio PCB's as RF amplifiers.

Essentially not bleeding off the RF to ground at the Detector and directing RF to the next stage.

Now to put the Fox in the Chicken House or more aptly the Bee Hive.
Them's that can, do, them's that can't, teach.
Technicians are hands on at the bench, Engineers theorize at the desk

When testing diodes with a simple digital meter with a diode checker function I sort of expect
to see 0.6 volts on a 1N4007 or a 1N4148

and buy germanium diodes for radio receiver circuits..... expecting something more like 0.3 volts.

The Russian diodes have stripes.... with no real pattern of always being on the cathode (-)

http://www.learnmorsecode.com/regen/diodesstripes.jpg
http://www.learnmorsecode.com/regen/diodestripes2.jpg

I thought that the idea that plain silicon diodes like 1N4007 and 1N4148 were not of any use in simple crystal radio circuits because they have that 0.6 voltage drop while the historic ...in every text book crystal radio circuit.. 1N34A was supposed to be half that voltage.

I did a comparison with 8 different cat whisker germanium diodes.
I have one that is a mystery.... no markings... so I just called it BULGARIAN.
My 1N34A diodes consistently tested between 0.38 and 0.4

The BULGARIAN diodes all tested real close to 0.6

While the Russian diodes where 0.32 to 0.38

and the Russian D311 (black beauties) were 0.23

AND
just for giggles I will toss in the modern SCHOTTKY 1N5711 at 0.27

I have used the 1N5711 successfully in the bare bones simple crystal radio...big coil with slider.

http://www.learnmorsecode.com/help/alldiodes.jpg

So it looks like the D311 is the lowest and I assume it would be best for simple crystal radio RF circuits...
but I hear no difference between any of these GERMANIUM diodes.... they all receive AM broadcast radio here.

http://www.learnmorsecode.com/help/D311diode.jpg

Hi
Thanks for the Response.
I know it will only work with a strong Local but it does add a little sex appeal/pizzazz to the Steampunk.

I purchased some Buzzers to use as a wide band signal generator to aid Cats Whisker in finding sweet spots. Since I would be adding a battery i am thinking of using it for a forward bias circuit to optimize the Detector(s) with a micro amp meter.

Thanx again

No – it was a screwdriver adjust, no knob shaft, locking collar trimmer cap. I did some simple modifications to make it more usable.
Some of us have made homebrew capacitors, but they're at the 'crystal radio' level, not really with the robustness or resetability or stability for VFO use.
I recall seeing somewhere advertised for the ham radio market, some kind of kits for transmit level high voltage variable capacitors, kits produced by some individual with I suppose, a well equipped machine shop.

Is the transformer required to drive the piezo element?

I stumbled onto this INSTRUCTABLE that shows how to make a piezo element vibrate on
anything... box... glass .. anything.....

but there is ZERO theory explanation of the parts.
I crushed the PDF into one image here:
http://www.learnmorsecode.com/regen7/piezo1.jpg

It uses an audio output transformer .... I believe it is 8 ohms to 2K ohms with the 2K ohm side attached to the peizo element.

Is this transformer required if I want to attach this
http://www.learnmorsecode.com/help/LM386amp.JPG
http://www.learnmorsecode.com/help/LM386kit.jpg
LM386 circuit to the piezo?

I see Epay has some Litz wire of 3000 strands. At around $38 a meter, you have to be a serious crystal radio experimenter to invest in that.
Due to language hurdle, we don't hear a lot about it here, but there seems to be a very enthusiastic following in China for crystal radios.
Back many years ago, when I scrounged a couple spools of 36 strand Litz, I felt I had scored a big deal, but now that's nowhereville.

Hi

Is there an Ebay Listing for the System?
Checking the Specifications of the Radio Shack Parts leads to an Answer of
yes & no.
The ultimate aim is to supply a significant amount of electrical power to a
transducer that converts to mechanical power.
The key is what is the Impedance of the Transducer?
Conventional Audio Amplifier take a low voltage, low power, high impedance
signal and converts to high power, low impedance, output, Loudspeaker(s).
Piezoelectric devices are inherently High Impedance. So in your case with a
conventional amplifier with a Low Impedance output the transformer is used
backwards Low Impedance to High Impedance

http://classroom.materials.ac.uk/casePiez.php

This topic has me wondering about the history of piezo earphone devices. I was looking at a B-A company catalog last nite, catalog from around 1938, and it
listed a pair of piezo phones, price then IIR $5.39 I didn't know they went that far back. Then I wondered when the small import piezo single earpieces came
in. I have to guess around mid 1950s or late 1950s, when the first Japanese "rocket radio" and other such "pocket crystal radios" started coming in. (I think
maybe the very high impedance of this output device made possible the crystal set usability without a ground connection, which I think made these a lot
easier to sell then the "Midway Company" pocket sets of the 1940s-1950s, with magnetic phones, and had ground and antenna wires.) I'm going to try to
nail down more precisely the dates of the inception of these products.
I recall there was an article in "Elementary Electronics" of yesteryear with a title of something like "Grow your own crystal earphone", which sounds pretty
intriguing.
Digressing – we discussed this on another group – IIRC B-A Company in Kansas City shows up in a scene in the movie "In Cold Blood", which was a dramatization
of Truman Capote's influential and best selling 1950s true crime account. This is in an early scene at the Kansas City bus depot where one of the drifters shows
up in town. This probably means something only to other OT types.

(LONG)ppppppppppppppppppppppppppppppppppppppppppppppppppp
Hello Hue,

I accept your challenge but must mention some "gotcha's".

Gotch #1 - I am presently building a "model" regen radio for my little friend, Jaxon. He lives next door, and is (just) 7 years old. I have to finish this project before I start another project. That's top priority.

Gotcha #2. I would like to make this exercise more instructive than a simple exercise in "OK, I did it - your idea worked." I want to understand the contradiction between your observation and Tom Lee's point. I'm quite sure both observations are reliable, and I need to understand why. I have three types of headphones here. (a) Australian military high-Z, WWII vintage. (b) some ex ABC (Australian Broadcasting Commission) hi-Z phones from who-knows-when. (b) some ex US army 'phones, probably ex some fighter aircraft (they have a VERY short lead). Identifiable (when/if I can find them).

I propose I set about discovering AND DOCUMENTING the lowest practical signal level my ears will hear using these phones. While there will be some subjectivity here (I'm the subject) I think the pico-watt sensitivity of these (and the working impedance) will be of some interest to every-one here.

Oh, I can also "mimic" your high-Z piezo 'phones by adding a JFET circuit in front of my old, moth-eaten (but much loved) headphones.

Gotcha #3. I have some modern lo-Z stereo phones, presumably 32 ohm working "Z". For these I say "as above". Except I'll drive them from an opAmp and just measure the working voltage.

Gotcha #4. To get real value from this experiment (and this is the hard part) I must measure the working "Z" for my aerial system and know the working "Z" for the 'phones. For the last item - easily done. For the aerial (and the detector), not so easily done. I have very little calibrated, sensitive test gear here. Some thought and care will be necessary.

I'm confident this test (or these tests) will demonstrate the accuracy of your observation. I think you have more experience with this vintage gear than me - but that doesn't worry me. If I do this experiment well, I'll learn something. But I don't intend to stop when I say, "OK, you're right." I happen to know that standard AC circuit theory works; and I think the first part of the experiment should measure the input and output impedances. Knowing this I should be able to make some prediction about the relative improvement gained (for example) by a full wave bridge detector, or a voltage doubling detector when compared with a common 1/2 wave detector.

So, we will need to do a little work setting up the experiment. We will need to choose the type of diode (and so on). I suggest we do that privately, by e-mail. After that we can post the results here, in the Regenrx "files". I should write an informal "hobby-style" report, such as you would see in a good quality magazine such as Ham Radio.

Les

About my version of Don's "slugsorb" reciever.

The idea is a simple radio that a boy can copy. I may have gone a little overboard on this - "my" version is a 3 transistor adaption of Don's circuit. His radio has two transistors. Three transistors may be a little too complicated for a 7 year old. More on that in a moment.

Construction: Wooden breadboard, with nails and wire.

My set is the "model" that Jaxon will copy. I used a layout that mimics the circuit diagram. I have an extra problem. Jaxon's sister (Emily) is jealous that Jaxon is building this modern marvel, and suggested she should build one too. So this project may take a week or so longer than my first plan proposed. That's life.

The extra transistor: I chose to add an extra transistor so it will work with modern lo-Z ear-buds, or common amplified speakers. I suspect that amplified speakers need 50 to 100 mV drive; but that's only a guess. At any rate they will have an input "Z" (I guess) of about 5k ohms. Again, I don't know, I've never seen a figure on this. That's the function of the extra transistor.

I want Jaxon to understand that things that work must be planned. I want Jaxon to understand that if he does "things" with his radio (like connecting the battery in reverse) it will stop working. I want Jaxon to have the fun of taking his radio to school and showing it in "show and tell". (I hope it comes back in a working condition!!). For a young man, this is part of the excitement of growing up. I think that's the experience of just about every-one on the RegenRx list.

PPS. Hue, I will write to your "cargo-kult" address!!

Les, wonderful !
Now, last things first. Why not downsize the youngster's project to 2 transistors? If you're using 32 ohm headphones, you still might be able to get useful output without a emitter follower circuit. Or even one transistor, if you buy yourself some of those little piezo earpiece things. Not very expensive at all.
For your local broadcast, one transistor would suffice. I think I might almost tend to go to a 2-transistor vhf superregen for the FM band, because that's maybe what young people are more interested in listening to. You do have to pay a lot more attention to parts and wire placement, though.

The US military headphones, see if they're marked something like AN-HB-1. You may be able to look up the impedance of all 3 with some online searching.
I believe the U.S. ones are 600 ohms.
Use any diode you find worthwhile. I don't think you need any advice from me at all. The antenna characteristics will be difficult unless you have some kind of impedance or antenna analyzer. I understand you want numerics but you don't really need them. I look forward to learning what your results are.
I have tailored my proposition to this: Use as high impedance headphones as you can find. Employ an input circuit that does a reasonably good job of connecting the antenna to the rest of the circuit. Then compare the half wave and fullwave voltage doubler and see if it adds to the output. I don't wish to tell you how to devise the tuned circuit and its matching capability. I will just repeat that in the real world, I found that a circuit similar to Heath's CR-1 and the Mackay Radio (ship radio emergency crystal receiver) very effective, much better than a tapped coil or capacitive divider. Some of the crystal radio designs out there just miss the boat for maximizing power. Like the one-size-fits-all input coil winding, or the variable capacitor to the top of the tuned circuit – hogwash, unless you want to cut down loading on the tuned circuit and so boost selectivity. My goal in my little set was simply to develop as much output as possible without going to the extremes. Actually, in crystal radios, volume is cheap, selectivity is harder to get.
Not at all that it's a big deal, but I might draw up my little circuit and give it to Rob to post. I think my notes on it are perhaps of more interest than the actual circuit.

One thing I been thinking about – again ! – is how to combine maximized power and micropower components to get actual gain in a passive receiver.
I have seen numerous circuits for this, some even claiming enough gain for a signal-powered regen, but for this they always have seemed to have a really good antenna and strong input signals. Many years ago I played with "enhanced detectors" using high current gain Ge transistors and I thought I actually had something, but didn't pursue it long enough to get a repeatable recipe.

28174. Regenerative IF stage question

Yahoo group: regenrx (2016 — 2017)
Date: 2017-05-23 00:21:18 UTC
From: Hubert Miller
Topic: 28174 Message: 28174

I have a question for people who have used a positive-feedback and control scheme like this -

1. regenerative IF stage, using pentode valve with suppressor grid raised above RF ground, such as Halli SX-140 and Knight 'Star Roamer', or

2. regenerative IF stage, with valve cathode raised above ground by an RF choke, and a pot parallel the choke for adjustable bypass;
the regenerative IF scheme used in the old Frank Jones radio manuals.

3. tapped coil regenerative stage, with a pot from the coil tap to ground, to control regeneration; has appeared in some regenerative receiver
project articles. Probably nothing remarkable about this method either for positive or negative.

I am interested in user experience with these 3 schemes, most particularly in how "smooth" advancing the regeneration into full oscillation
proceeds, and maybe if any stability problems. I am thinking of adding a slight modification to a TRF HF receiver which needs better selectivity
to be practically usable, and to do this with minimum modification. Using one of the first two schemes above. thanks- Hue

Hello Hue,
Can't answer your specific question (since it relates to I.F.) BUT ...

Following Arnie Coro's advice I tried the regenerative Hartley detector with a varying voltage on the screen grid.

Tube: 6AK5.
Regen control: Pot in the screen grid line.
Method of feed-back: Tapped coil, per Hartley detector. (Said that before).
Effectiveness: Very smooth control. Between oscillation (12 volts) and no oscillation (9 volts).
using a 20k pot. BUT take note: My B+ supply is only 36 volts on this receiver.

I have one of those (very very expensive) Hallicrafters S-38 receivers (original, no model letter).
I intend adding a "Q" multiplier to this set.

There is a regen detector (solid state) with a very effective "Q" multiplier (one transistor taps onto the "grid" of the JFET detector via 33pF cap). This would be a "nice" way to add regeneration to ANY simple set. I plan to do this to my (very very expensive) S-38. (Original - no model letter!!!)

28182. Re: Question: high-gain broadband RF amp between Q-multiplier and detector?

Yahoo group: regenrx (2016 — 2017)
Date: 2017-05-24 10:53:23 UTC
From: dawmast@...
Topic: 21752 Message: 28182

"I'm thinking about the following design: Q multiplier, followed by a low-input-Z, high-gain, broadband RF amp connected to a low-impedance point on the tank (through a capacitive divider). The output of the high-gain RF amp then goes to a common-emitter BJT biased to serve as a detector.

Why all the complexity? Because a separate BJT detector stage has such a low input impedance (~2k at 30 MHz, according to simulations) that it should not be connected to the top of the tank, and connecting the BJT detector to a low-impedance point at the tank yields such low signal voltages that efficient AM detection is not possible (according to simulations with microvolt-level signals at the tank). So, why not use a high-gain, broadband RF amp between the Q multiplier and the detector to boost the low tank voltages (taken from a low-impedance tapping point) up to a high level for efficient detection?"

Dear QRP.Gaijin, have you already got a circuit diagram of this receiver and would you like to post it here?

Topic: 21752 Message: 28183

Hi drm1173,

Thanks for your interest. Unfortunately no I did not (yet) complete this regenerative receiver with broadband RF amplification before the detector. Instead, I am now thinking that a more interesting way to achieve this goal is with two regenerative stages -- the first one acts as a Q-multiplier to boost the RF signal (maybe by up to 40 dB?), and the second regenerative stage actually acts as the detector (changing RF to audio). I think this is the same idea used in the "Cascade Regenerative Receiver" by WD5HOH.

Furthermore, I will probably try this idea in a superhet. In other words, I plan to have a frequency converter to convert shortwave signals to 2 MHz. Then, I will have one 2 MHz Q-multipler followed by a separate 2 MHz regenerative detector. The signal boost from the first Q-multiplier should make the second regenerative detector quite sensitive. Furthermore, the first Q-multiplier should be able to act as a simple AGC stage by using the detected AF voltage to pull down the Q-multiplier gain if the detected audio is too large.

Probably, the big challenge will be keeping the two regenerative stages isolated well enough to prevent bad interactions. I hope common-base buffers will be enough. If I succeed with this idea I will report on it.

Best regards,

Hi,

I think you will just overload that regenerative detector. Unless you use a diode mixer at frequencies higher than 20 meters you will have no need of "high amplification" ahead of a regenerative detector. I am a 40 meter ham and no rf amp has ever been desirable except for isolation from the antenna (no high gain amp) up through 14+ mc. That is regardless of the detector topology.

I think you will get better results using the inductors in the front end of your radio to accomplish impedance matching. If you suspect that you have some brand new, untried idea please build the hardware and let us know how it works. Enquiring minds want to know :)

Hi,

I plan on using tiny ferrite rod antenna (about the size of an AAA cell) with no external antenna. So, signals will be much weaker in my set than in a set with a proper antenna. Surprisingly, this tiny ferrite rod works fine for shortwave reception in the evening when wired into a normal regen. But in the daytime, signals are much weaker, which is why I think some RF amplification ahead of the detector will be useful -- with extremely low signal levels, square law detection works against us.. AGC is then useful to account for the vast differences in signal strength between day and night.

Best regards,

qrp.gaijin@yahoo.com
http://qrp-gaijin.blogspot.com http://qrp-gaijin.blogspot.com

28187. Re: [regenrx] Radio Shack "Globe Patrol" review ?

Well, yeah. it did all of what you state. However, i had fun with mine as it was my entry into SWL and DX. In addition to achieving WATVS (worked all tv sets) in the neighborhood, i was able to hear quite a few SWL and amateur stations with a bedroom mounted dipole cut for 11M (CB) and fed with twin lead. Also managed to connect onto my TV antenna (versus the main one for my parent's house) and heard quite a few more things. The regenerative set taught me how to tune a station to receive CW and SSB. I had managed to tinker the receiver to death by changing components and seeing what happened. My entry into RF electronics. Kind of wish i still had the receiver as it seems more capable than some of the portable commercial radios i possess today.
73,
kevin
kc6pob

I wonder if anyone here has used
the Radio Shack "Globe Patrol" radio. I just
batteried up one I bought at a swap.
I am kind of underimpressed. I
don't know if it always worked like this or some parts
have degraded or changed value.

I find the regen control the opposite of smooth; I'd
call it "abrupt", the fiddly way that gave
regenerative radios a bad

name in their later kit years. It
also seems to have quite a bit of sensitivity to hand
capacitance on tuning. I will have

another go at it after dark; not
much on now. Of course at this price level there was no
reduction gearing on the main
tune or bandspread controls, so
probably much of my unhappiness comes from comparing it to
tuning an ex-military
regen set. This example seems to
very neatly built, but I note the main tuning is a poly
type, low Q, and the bandspread
cap looks really low quality, very
chintzy.

Maybe later I'll have a look
at the schematic and see if there's room for
improvement, at least in the critical

regenerative RF stage. Should be
at least possible to improve that gain action in the regen
stage.

-Hue

28188. A tiny ferrite rod antenna at shortwave

Yahoo group: regenrx (2016 — 2017)
Date: 2017-05-25 10:21:57 UTC
From: qrp.gaijin@...
Topic: 28188 Message: 28188

Hi,

I recently built a shortwave regen with a tiny ferrite rod antenna (type "SL-45GT" for AM BCB use) as the tank coil. The reception was surprisingly good for such a tiny antenna that was not even designed for use at shortwave. Here are some low-quality videos to give a rough idea of the signal levels possible with the tiny ferrite rod antenna at shortwave (around 7 MHz).

https://www.youtube.com/watch?v=KyAlpqw-fGM&feature=youtu.be
https://www.youtube.com/watch?v=KyAlpqw-fGM&feature=youtu.be

https://www.youtube.com/watch?v=eENrSUPxg1M&feature=youtu.be
https://www.youtube.com/watch?v=eENrSUPxg1M&feature=youtu.be

Note however these signal levels are in early evening. In the daytime, signal levels are unfortunately much weaker.

I may dismantle this receiver soon (trying to convert it into a superhet), but I thought it was worth preserving a video of its performance. Sorry for the low-quality video -- I was recording directly from the crystal earphone.

Best regards,

qrp.gaijin@yahoo.com

Date: 2017-05-26 10:35:43 UTC
From: les.au49@...
Topic: 28174 Message: 28193

For the circuit see RegenRx files.
Look in the folder: Solid State Regen Ccts
The file is: TRF Regen Rx, with FET det & 'Q' multiplier.
The detector is either MPF102 or 2N3819.
The "Q" multiplier is PN2222 bipolar transistor.

Hope this helps.

Les

Here I have another regenerative receiver based upon a Q-Multiplier with a FET T2 and a separated BJT detector stage T4 in which a source follower buffer stage T3 has been inserted between tank circuit and detector. This emitter follower detector T4 has a good AF quality. T5 is a current source which sets the standing current through T3.

Hi Gaijin,

Nice reflex receiver experiment. This type of receivers can be ferry sensitive.
AM antenna rods has a initial Mu of aprox 120 bud the RF loss will increase a lot at higher frequency. An option is to use a ferrite rod from an old PAGER receiver (tell you there is telephone for you) they has been working on 70 MHz and those rod’s has a low loss factor up to 70MHz. And a Mu-initial of aprox 40..
It should be possible to cover the reflex in the higher SW band 14Mhz..or higher.

In the KTH-rf Design files a photo of an experimental reflex receiver based on 2xBF1105 FET’s and 1xTDA7050 lf amplifier under construction. Important is to build it in an aluminium box prohibit hand affect.
The detector is ceramic tuned by a Polyvaricap
All in SMT and working on 3.3 volt. Should be wearable 45X45 mm size.
It is fun to do these experiments. Have still to complete and test it.

28206. Obituary(s) To A Filter Cap And A 6X4 Rectifier Tube

Yahoo group: regenrx (2016 — 2017)
Date: 2017-05-27 20:13:01 UTC
From: Sam Neal
Topic: 28206 Message: 28206

Hello,

I sadly report the passing of two QRP radio transmitter components.

(#1) Passing (Suddenly!) of a 22 mFd/450 Volts DC Filter capacitor.

Born approximately 2007 in China (The People's Republic There-of)

Passed (suddenly) just before the 4 States QRP Group Net, 0130 Z - 7122 kHz
-
24 May, 2017 at 01:15:05Z

Born in People's Republic of China to operate continually at 450 VDC.
Passed suddenly and in a spectacular manor while operating at approximately
380 VDC

We also sadly report the associated passing of two 1 Ampere fuses and one 6X5
Tube.

(#2) Suddenly, 01:15:06 Z one 6X5GT/G CHS/Jan rectifier tube.

6X5/GT/G/JAN/CHS served proudly during the World War 2 conflict assigned to
the United States Navy.
Two innocent 1 Ampere fuses lost their lives as a result of the above
incident.

Services will be This coming Wednesday by the P&H Garbage Pick-up Service
Company
Pall-bearers will be Cooter and Bubba.

Internment will be shortly there-afterwards at The Liberty County Texas
Landfill

==========

This is the first failure I have had with these small sized fiter caps. I
suggest operating these imports will below heir rated Voltage limits. The
above components were in the built-in power supply of a clone-kit of an Ameco
AC-1, with a Ken-Rad 6V6 tube as a crystal oscillator.

The transmitter was not being used when the filter cap failed, just minding
it's own business, awaiting net time.

The current rush took the 6X5/G/GT with it, and it's rolling off the desk top
and playing Humpty Dumpty didn't help it any at all. So far, no problems with
the replacement 22 mFd. 450 VDC cap.

All kidding aside, have any of you had problems with these type capacitors, operating well below their operating Voltage, failing? The value and Voltage ratings are well marked, but no manufacturer's info is shown. I either bought them in small lots off of E-Bay purchases, or the filter cap was supplied with the kit - I forget.

Due to failure with 50+ year old paper filter caps in older boat anchor rigs, I routinely replace the filter caps and also add a fuse before ever transmitting the first dot with them. I had hoped that operating well below it's Voltage rating would help, but it didn't.

Any comments on similar incidents would be appreciated.

73,

Sam Neal N5AF

Good day Joe,

I strongly recommend NO-ONE builds a B+ supply without a power transformer.

This topic has been discussed many, many, many times, and a transformer-less power supply is dangerous.

Transformers are cheap (free if you care to look carefully), and with some imagination just about ANY transformer can be made to deliver 90-120V (or more) with an imaginative rectifier. More on this later.

Just about ANY regen receiver will work nicely from a 90V B+ supply.
The ARRL hand book has some very nice (simple) circuits running from a 48V B+ supply (look in any handbook from the 1940s).

Les

PS If you can find a 24V AC "wall-pack" supplying 500mA, build a 1/2 wave doubler or tripler and you'll have an inexpensive, effective power supply for any regen set you care to build. If you use x2 12V tubes and wire the filaments in series you will also have a heater supply for your set.)

Hello,

I agree! Also, it only takes a few minutes to add a fuse/fuse holder - an excellent investment - considering my recent power supply filter cap failure where the fuse saved the transformer from destroying it's-self. The fuse saved the day for me.

Hello,

You can easily get 90 - 120 VDC by snapping together the needed amount of 9 Volt transistor radio batteries.

Topic: 27987 Message: 28212

Hi Sam,

I often (always) run my "ARC5" command receivers on 90 volts worth (10 in series) of 9 volt batteries. The current draw wide open is about 15 mA. Most tube gear (high power TX amps excepted) are very happy with 90 volts. Some will run on B+ as low as 12 volts. I have not been masochistic enough to try that! One of my command receivers worked at 45 volts (5 X 9 volts batteries) at 8 mA current. But performance was noticeably *down*. Looking at tube specs and battery operated radios I think almost all tube can perform well at 45 volts B+ and existing gear can be modified for appropriate bias and screen voltage to do a good job on 45 volts B+. I do not care to modify my antique mil radios any more than they might already be.

I have used 20 of those batteries in series to get 180 volts B+. The battery pack can be clumsy to deal with but is manageable. I only did that as "proof of concept" A 'permanent' container should be built just for the purpose. There are some QRP tube transmitters built with tubes that use the 90 or 180 volt series battery packs that are practical to operate. Power levels are around about 1 watt of output. I am planning to build one and give it a go. I will be using "battery" tubes and three or four of those tubes can run a long while on a flashlight battery. I would only use the larger 180 volt battery pack to get longer operating time from a transmitter. The receiver operate for *weeks* at 90 volts. A qrp MOPA should draw less than 30 MA at 90 volts B+ and much less at 180 volts ~15 mA or less - for three tubes and CW. Less two tubes.

I see 9 volt batteries priced at 4 or 5 bucks each and I *never* buy those. It is expensive enough to buy them at a dollar each for alkaline batteries. I sometimes find for them under a dollar each.

So it seems that power supplies for tube radios do not *always* require a power transformer <sly grin>.

Hi, group,

Rob (kb3by) obliged me by sending me a complete kit for his version of the little Kitchin regen receiver (http://www.learnmorsecode.com/regen/00regen.html http://www.learnmorsecode.com/regen/00regen.html).

Due to a public holiday on Thursday I was able to spend some time and fired up my soldering station.
I have taken some pictures which can be accessed via my own website at
http://www.k-code.de/images/Kitchin_regen.html
http://www.k-code.de/images/Kitchin_regen.html.

Rob very carefully prepared and wrapped the kit for me.
After I printed out a template for the circuit board layout, soldering didn't take longer than an hour.
All parts are of ordinary size, however, I had to use a magnifier due to being farsighted.

Now here's my problem : I can't seem to get the little receiver working.
It simply won't go into regeneration at all.

Since I planned to use it for the NDB-band (200 - 600 kHz) I thought it would be a good idea to first test it with the Coil and capacitor mentioned in Kitchin's document.

However - not working at all.
I swapped the ends of the tickler coil - did not help.
I checked all components incl. the correct assembly of the three electrolytic C's, transistors and diodes.
The receiver draws some 12.5 mA from a brand new 9V battery.

I have absolutely no idea what went wrong.

Would someone on the list be able to help where to start to search for the fault?

Thanks very much in advance.

73s

Joachim

30 mA is a pretty heavy load for the 9 volt batteries, isn't it? I think the average draw on
them in the old "pocket radios" they were intended for, was about 10 mA average, no?

I suppose since the mode would be CW the average drain would be much less so not so bad for their life. Still, being hit with a 30 mA draw is hard on them.

I suggest the dollar stores. You can get 2 for $1 there.
BTW, I bought some D-cell battery boxes recently to power up various things with 1.5 or 3 volts DC. There were some interesting looking ones that could snap together sideways or in series so you could get various voltages and current capacities, however the reviews of the side-to-side snap battery holders had a lot of negative comments, so I chose separate battery holders with wire leads coming off. The price was quite low. In the past i have even soldered right to the battery, but that's not the elegant or flexible way to go.

Which reminds me, I have a couple VTVMs with soldered in 1.5 volt batteries, and I should replace that system with a battery holder instead.

Side by side birds-eye view looks to me like all the parts are there.
All FOUR of my KITCHIN PCBs heard Radio Havana Cuba on 6Mhz VERY LATE
at night.
But are deaf in daylight hours hearing only AC static hum.
Perhaps it works..but only late at night when skip is coming in?

28216. Simplest crystal filter performance ?

Yahoo group: regenrx (2016 — 2017)
Date: 2017-05-29 00:30:41 UTC
From: Hubert Miller
Topic: 28216 Message: 28216

Gang, Les sent me schematic of a three-valve, 4 stage receiver: 6K8 converter; 6C8 BFO and audio; 6J7 regen detector.
The schematic doesn't have parts values. So anyone - including Les - I am specifically interested in the
range of frequencies that the crystal could be in, and - -
the value of the crystal load resistor, which is also the 6J7 grid leak.

It seems to me the value of the grid leak and the crystal load are at opposite goals: the higher grid leak makes for
more sensitivity (at the price of poorer strong-signal handling), and -
the crystal performance is diminished by higher values of load resistor.

I watched a video by Mikrowave1, title something like "Command Sets #4", where he was investigating selectivity
improvements for this WW2 aircraft receiver with a 2830 kHz IF. He put a 2837 ex-2 MHz marine band crystal in
the pluggable IF can and got great results, "narrow SSB filter" selectivity, but his circuit uses a tapped input coil,
phasing trimmer cap, and a load of something like 56k. So I am kind of wondering how the single crystal, no frills,
high load impedance works. I don't have the time or equipment to do a selectivity sweep now.
This is not the first incarnation of the no-frills series crystal filter I have seen. I believe I saw an article in CQ magazine
from the 1950s titled "Mobile Selectivity" where a crystal was inserted between the shortwaves converter and the
car radio, and then in another CQ article, or book from the 1980s a 455 rock was simply inserted in series in some
simple 80 meter SSB-CW receiver project.
So I suppose I'm wondering what the passband curve of a single crystal would look like, also.
thanks-
Hue

Hi,

See the article I did a number of years ago on a "Poor Boy's Crystal
Filter". I'm sure that it's performance will be different for a "Hi-Z"
load resistor in a Hi-Z grid circuit though.

28219. RE: [regenrx] Simplest crystal filter performance ?

Yahoo group: regenrx (2016 — 2017)
Date: 2017-05-29 02:06:17 UTC
From: Hubert Miller
Topic: 28216 Message: 28219

Phil, yes, that's what I mean. I am aware this is easier to do and have success with at 455 kHz than say, 2830 kHz, particularly about skipping any
phasing capacitor, but I don't have any specifics. (My handy-dandy Shure Bros. slide rule says 10 pF at 0.5 MHz ~= 30K, while 10 pF at 3 MHz
~ = 5K ohm.
The "Command Sets" video narration said that with the crystal filter and phasing cap, it was "almost too narrow" for non-contesting SSB. I was
thinking, if that's the case, he could have increased the value of the load resistor.

Just curious - what is the load value in your receiver, the one with the added 455 kHz rock?
I see some filter loads that are resistive, think I have seen some that are purely capacitive.

I just now put a 2450 kHz rock on my LCR meter and it says 17 pF. I don't know what the crystal package is called; it's a boat radio crystal larger
than FT-243. I don't have any FT-243 or HC-6 around to check. I sort of conclude that for crystals in the region ~ 0.5 MHz, okay to omit any
'phasing capacitor, but for around 2-3 MHz up, you want to phase out that crystal holder capacitance.

Hi
Rechargeable Batteries

My $0.02 and then on to Stephan's Article

Low Self Discharge AA Batteries with inexpensive AA to D adapters as well as AAA to C.

There are rechargeable 9 volt Batteries but they are a bit pricey.

Low Self Discharge ALKALINE. A solution looking for a problem.
A niche market for medium duty discharge that gives a full 1.56 volts but cant sustain the surges like the more expensive 1.2 volt Eneloop Low Self Discharge NIMH Batteries.

Great for Flashlights, regular use and in Emergency Packs,Clocks Stereo and TV Remote Controls Portable Shortwave Radios, no noise from AC power packs,RC Control Transmitters not Vehicles.

73 de Jordan ve7jjd

http://stephan.win31.de
Sanyo Eneloop rechargeable's
For someone who likes to use his portables on batteries yet would not like to waste a bunch of primary cells, rechargeables are the power source of choice.
Now conventional NiMH types have a number of drawbacks, one of the biggest ones certainly being high self-discharge rates (even more so in current high-capacity cells than in those with about 2000 mAh or less). If you have a drawer full of radios that may not be used for some time, you can bet that by the time you want to use a particular one, its cells will be almost flat yet again. That doesn't get any better with age, and if you've got some damaged cells in there, it's even more fun. (Again, the very high-capacity stuff has proven quite unreliable, being easily damaged by overcharging. Out of two sets of four 2500 mAh Sanyo cells for camera use, always charged in a "good" charger not known for blatant overcharging as long as the cells were halfway low resistance, a total of three cells showed excessive discharging indicative of internal leakage. Sure enough, the camera always complained about empty batteries pretty soon whenever it was used.) A good occupational therapy. Conventional NiMHs should be called "chargeables", since that's what you end up doing most of the time…
To the rescue came Sanyo's Eneloop cells, the first exponents of the new crop of NiMH+ / "low self discharge" / "ready to use" cells. First introduced in Japan late 2005, they slowly became available worldwide the next year. Nominal capacities include 2000 mAh in AA (R6) and 800 mAh in AAA (R3) size, with C and D sizes being covered by mechanical adapters (C and D sized cells with minimum capacities of 3000 and 5700 mAh and

PTC-based short-circuit protection were eventually announced in 2008, suspected to contain three AAA or AA cells each, respectively). While capacities were somewhat smaller than what was available in conventional NiMH cells, they soon built a reputation for low self-discharging, low internal resistance (with decent performance even at low temperatures – the product launch "down under" was staged in an ice bar, now how cool (literally) is that?) and excellent matching that made creating hand-matched sets of cells redundant. There have also been very few reports of failures (which is to say that I haven't been able to find any, just statements of very low failure rates).

Pricing of Eneloops is about 10 EUR for a set of four AA or AAA cells. Competing cells, marketed under quite a number of brands but only manufactured by a handful of OEMs, typically have a specified capacity of 2100 mAh in AA size and somewhat worse properties otherwise. They do not all appear to be as rugged as the Sanyo cells.

Currently I have several sets of Eneloops in use, mostly AA (plus 4 pieces AAA), first bought for my camera (a somewhat picky beast) and then displacing more and more of the conventional NiMH cells in my radios (currently none of the 2500 mAh Sanyos are in use and all of the crappy old 2200 mAh noname cells have gone to recycling, but some 1850 mAh Sanyos bought as NOS remain). Do they live up to their reputation?

In a word, yes. While they will eventually lose some voltage when sitting around for a while (but then still give off plenty of charge even at untypically low levels) and I guess internal resistance will creep up as in conventional NiMHs, self-discharging is much reduced, and so is the number of extra charging cycles – actually, I don't think I've recharged any of them for anything but "real" current drain from the devices they were used in. In both my little Olympus (2x AA) and my dad's Fuji (4x AA), they keep on going and going. During charging at 700 mA, they do not get overly warm, and end-of-charge detection works reliably (the charger has a habit of failing to do this given cells with high internal resistance). Voltages and capacities stray very little between cells, to the point that they may be within a mV even after some time. Accidental deep discharging happened once or twice so far, from which the cells seem to have recovered well.

Failures? None so far.

The verdict? Eneloops have definitely made life with rechargeables a lot easier. They go a long way towards closing the gap between conventional NiMHs and the user-friendliness of lithium based cells. You still need a decent charger for them and deep discharging should be avoided as much as for other NiMH cells, but other than that they're pretty much bulletproof.

Recommended? You bet!

Postscript: By now, you can also obtain higher-capacity "XX powered by Eneloop" cells with 2500 mAh (HR-3UWX, vs. HR-3UTG for the "classic" Eneloops or HR-3UTGA for the 2nd-generation ones). These are mainly geared towards digital cameras and such, with the expected results of thinner membranes: Higher self-discharge rates, less cycles, less robustness. Inner resistance still seems fine though. I think us radio nuts are better off sticking with the standard types, which are cheaper to boot (plus you can also buy them in flashy colors if you're so inclined).

Hi

Thanx
73 de Jordan ve7jjd

Hi,

The 30 mA figure would be for three tubes all at full power (only the final would be) and less than 50 percent efficiency - a worst case. It is not difficult to beat 'less than 50 percent'. I will have to look up the specs to see if the current drain was given for the two-tube mopa project. The oscillator and any buffer tubes will not be running at one watt output. I can't report exact results because I haven't built, tested, and used the TX. Recalculating just the current draw for the final at one watt and 50 percent efficiency (can be surpassed) comes to 15 mA. I will report back here when I can get that project finished.

For my command receivers I use rechargeable 12 volt "SLAB" batteries for the heaters. I could also build a solid state multivibrator B+ supply - exactly like a solid state mechanical vibrator supply with a 12 volt source. The 90 volt packs last me a long time. I have observed that they will still run the radio when 10 of them have dropped below 75 volts at full load. 1.5 volt cells would be much larger in any kind of series pack as 60 of them would be required for 90 volts. If the dollar store 9 volt batteries suffer a drastic price increase, the multivibrator supply is the way I will go. Rechargeable 9 volt batteries don't perform very well. Given my previous experience with them I am unwilling to buy ten or twenty of them for this kind of a "man's job".

Always be aware that batteries left sitting for long periods of time (months? years?) do unpleasant things. The least being "won't work any more".

73,

Bill KU8H

28223. RE: [regenrx] Re: Two tubes

Yahoo group: regenrx (2016 — 2017)
Date: 2017-05-29 04:44:07 UTC
From: Hubert Miller
Topic: 28214 Message: 28223

I want to issue a slight "maybe" to your post.
I do store my batteries in the refrigerator.
However, I used to work in the telecom industry. I used to grab discarded 45 volt batteries after they no longer met the self-test standard
in the special test set using them. The self-test was that they would short circuit drive 1.5 amps! These are ordinary B size batteries, I don't
have one handy right now, but they're about like 2 of the old 67.5 volt batts pressed together.
I still have a couple 12-pack boxes and these are from 10-20 years old. They will still power some tube receivers that only use around 10 mA.
For years I was giving them to a friend to power his GRC-9 receiver.
I just looked at some "1.5 volt ignitor" batteries that are resting in my fridge. The date code is 0111 which I assume - guess may be 2011 or
2001 - I think it is 2001 tho. They still have a charge strong enough to light an LED to full brightness. I keep them around for eventual use
with one of those little one-tube radio kits I have.
No - I don't know how long the 1.5 volt batt will last, but "the price was right".
And the 45 volters, under the low drain I specified, last many hours.
-Hue

>Always be aware that batteries left sitting for long periods of time
(months? years?) do unpleasant things. The least being "won't work any
more".
73, Bill KU8H

28225. Re: [regenrx] Re: KITCHIN regen version 4

Yahoo group: regenrx (2016 — 2017)
Date: 2017-05-29 12:35:50 UTC
From: Michael
Topic: 28008 Message: 28225

Joachim,

The main claims for the floating-diode Kitchin are

- high sensitivity
- relatively simple, low-component design

If sensitivity is low, somewhere the build may be
less than optimal as some emulators report good success.

Low sunspot activity currently affects propagation,
so different SW bands should be tried. Around 6-7MHz
there is always "something" to be heard in Europe.

The Kitchin design is controversial because of the
unterminated Ge diode. So the unpredictable effect of
"invisible" termination through leakage may be signnificant,
as are the individual characteristics of the Ge diode employed.
The other suspect is the coil, the design of which may
be critical.

Joachim, weiter forschen!

Hopefully, you will find the elusive answer, which will
be of great interest to all of us.

From: les.au49@...
Topic: 28227 Message: 28227

Hello Hue & list readers,

Hue - I sent a circuit (but without parts list) by email. You asked for more detail PLUS the parts list.
This posting describes how to get that detail.

First, the article of interest came from W0VLZ and Mr. Google will find that page if you want the original.
Look for improved 3 tube superhet.

Alternately, look in RegenRx files - zTemp. If you use Firefox to open the only HTML file and go to the end of that page you'll find a link to W0VLZ's page. That link worked on my computer 5 minutes ago. If you look for a link to an improved 3 tube superhet you'll see the info you seek.

Description. Photos. Circuit. Parts list.

The images in the HTML file I posted DO NOT LOAD.
If you want to see the images, I put them in the sub-folder named 1941 beginners receiver (or something like that). I experimented to see if I could post a complete, working HTML file. The answer is 'yes' that can be done, BUT I didn't do first time!!

I think the 3 tube superhet represents a good balance between simplicity & performance for a homebrew receiver. A regenerodyne may provide superior performance on 20m and above. The Jones superhet may provide better performance on 80 & 40m. That's my view.

Les

28229. hartley low-voltage regen?

Yahoo group: regenrx (2016 — 2017)
Date: 2017-05-30 18:45:42 UTC
From: msalbert@...
Topic: 28229 Message: 28229

I've been looking at some low voltage regen designs, and noticed that the ones I found are using separate tickler coil designs (vs. tapped coil Hartley). Is there a particular reason for this? Here are links to a few examples . . .
http://makearadio.com/tube/1-12af6.php
http://www.skywaves.ar88.net/homebrew/12Vregen.htm
http://www.qsl.net/kl7h/12v.htm
(QST also published a low-voltage, space charge tube superhet/regen design in 2003 that used a tickler)

These are mostly using 12 volt space charge tubes. I'm attempting get one going using a 32 volt DC supply using only junk box parts. I've given myself a limitation of that's the highest voltage I can use; hopefully that allows me to enter the standardish-tube realm. My plan is to start with a 9GH8 tube, using the pentode as the detector and triode for audio amp. If I can get this going then maybe other odd ball tubes will follow to make up the heater string. . . . 6GK5 as a GG RF amp and 15CW5 (aka PL84) audio amp stages . . . end result being a 1-v-2.

I welcome any comments / suggestions; thanks!

Regards,
Mark KB9VKE

A few years back, I made a Hartley receiver using 24v, a 12AT7, and a 12AU7.

It worked decently, although it didn't seem to oscillate at the higher end
of the short wave coil. I did hear some short wave stations there.

Overall, I think it's a worthwhile project.

Hi
It will be interesting to see the responses.
Since the original invention used Tubes and Tickler Coil I suspect the
majority of modern Designs and Homebrews followed suit.
I suggest surfing Ebay for a low cost medium high voltage wallwart.

http://www.ebay.com/itm/172673096275?_trksid=p2060353.m1438.l2649&ssPageName=STRK%3AMEBIDX%3AIT

*iGen-Max Two Tube Regenerative Radio Kit ! (**Version 4 - **New for Jan 2014)*

Tube regenerative receiver based on original 1930's design, with a modern twist, Varactor tuning and a solid state audio amplifier.

- If you ever wondered how those early radio and wireless receivers from the 1920's worked, then why not build your very own.
- The whole set runs off 12 volts so is *absolutely safe to build and use*, no nasty high voltages, it is a great way to learn a new hobby!
- Easy assembly all the components are mounted on a high quality silk-screened fiber glass printed circuit board
- No coils to wind that has already been done for you!
- Simple follow instructions with both schematics wiring diagrams!
- You get a manual, all the parts including valve(s), sockets, jack plugs, tuning control, coils, resistors, wire, nuts and bolts etc.
- Complete with high quality silk screened double sided printed circuit board.
- This kit is also available with optional add-on SW Coil Kit

Specifications

- Type: Two Tube Regenerative Hybrid Vacuum Tube and Solid State Amp
- Tube #1: RF Amplifier stage
- Tube #2: RF Detector stage
- Tuning: Two Stage RF and Regen Varactor Diode Tuning
- IC Amp: 1/3 watt Audio amplifier stage
- PCB: high quality silk screened printed circuit board
- Power 12V DC Batteries or optional 12V Mains Adapter
- Coverage: Broadcast Band / Medium Wave (Optional SW Coil Add-On Kit)
- Controls: Regeneration, Volume, Tuning
- Connections: Aerial, Earth, Speaker and Headphones

UK Designed

*Download the full manual from our web site **download manual* <http://www.6v6.co.uk/archive/manuals/iGen%20Max%20Manual.pdf>

Shipping UK - Items are sent Royal Mail or DHL.

Shipping International - Items are sent "Small Packet" or DHL
International. Insurance can be added if requested.

Combine your purchases and save on the shipping, please notify me at the
end of your first auction that your bidding on other items, when your ready
I'll combine the items into one shipment for you. Missing or Damaged Items

We take care to pack all items appropriately, and ship stuff all over the
world, so far nothing has gone missing or arrived damaged. Claims for
missing/damaged items will only be entertained if buyer has requested
insurance and recorded delivery. All larger or more expensive items will
always be shipped pre-insured by a courier and recorded, unless
specifically requested not to be by buyer.

Jordan, thanks for posting this. I was predisposed to be very skeptical of such a kit, but I'm actually impressed, at least by what I read.
The company is generous for sharing the complete manual online. I copied the schematic for my files even if I don't get the kit – but
I am curious enough about the performance that I probably will buy it. I recall that when Ramsey was a going company their online
manuals had a blank page where the schematic was.
I note that altho this kit has an RF amp stage, there's no attenuation control. Maybe at 12 volts B+ the gain is so low it's not a big
problem, and also it talks about 10 to 30 foot antenna.
The only thing I could ask for is for a kind of front panel, made of PC material soldered to the "floor" PC, like the way I think Howes
kits do.

Hello Mark,

On this list you'll find a description of a simple receiver that runs from a 36V B+ supply. Search, using the keys Hartley + Coro. That's "our" prof. - Arnie Coro! This advice is very good.

I built a set along the line Arnie suggested - with some mods. This is what I got.

A Jones superhet - frequency converter/mixer + regen detector + AF (buffer) stage.
Mixer: 6AK5, similar in design to that shown on David Newkirk's page (so 7 pin tube, not octal).

Regen detector, following Prof Coro's description. Hartley config. Regen control: A 20k pot in supply line to grid #2. I followed David Newkirk's advice: the reactance of my tank circuit components is about 125 ohms at the I.F. frequency. My I.F. is/was 2015khz. The detector performs as Prof Coro described in his posting. It is sensitive; the regen control is silky-smooth. My B+ supply is +36V regulated.
I use a regulated supply. Bill Cromwell told me, "Les, you must use a regulated supply!" So I did.

Then, following the detector I have an emitter follower to buffer the signal. This means I can drive a low-Z transistor amplifier without degrading the signal. So (either) hi-Z phones or an AF amp.
Solid state AF amp. (I think Prof Coro is shaking his head when he reads I'm using transistors!).

Now astute readers will say, "Les, Les, you have a converter, but no local oscillator!" True - I didn't write about this. My LO is solid state. (Sigh.) Now to comment about performance.

My interest is AM BC band and 80m. With a short aerial (perhaps 6m - indoors) I hear a 10kW station at the low end of the BC band that is about 100km distant. Any time of day. On 80m I can hear 1500km up and down the east coast of Australia in the evening. I run the filaments (wired in series) from the B+ supply using the appropriate dropping resistor.

Would I build this design again? Ummm .... definitely, yes, but I'd probably pick a regulated 24V DC supply and boost the B+ line to 48V. I would build the power supply (and AF amplifier) on a separate chassis. I wouldn't use +12V for the B+ line if I could avoid it. That low voltage is a novelty. Running a "tube" set on 12V is like driving a Gogomobile. It will get you there, but why not use a normal, garden variety, car? If you want to use your set away from the mains, use a 6/12V filament supply and invert the battery to +45, +60V or +90V. You set will perform much better on a 45V supply than on a 12V supply.

That's my experience. One final word. When you build your set, focus on solid construction. Use high quality parts. Build a solid (metal) front panel. Put your finished set in a box that shields it from drafts and breezes. Use heavy wire that can't wiggle or wobble. Forget

you're building a 2 or 3 tube set. Build it as if you're building a 10 tube "special". Use an expensive dial. You won't be disappointed.

Les

http://www.ebay.com/itm/172673096275?_trksid=p2060353.m1438.l2649&ssPageName=STRK%3AMEBIDX%3AIT

Nice design, almost EMP-proof :-) I would probably have
omitted the RF amp and used a second valve for AF - as I
did in my pre-shaving era, with a 22.5v HT battery.

28237. ABOUT REGENERATIVE RECEIVER CIRCUIT FOR OPTIMUM OPERATING VOLTAGE

Yahoo group: regenrx (2016 — 2017)
Date: 2017-05-31 10:57:51 UTC
From: Prof. Arnaldo Coro Antich
Topic: 28237 Message: 28237

Hi amigos ! Link does not work here , it comes back

with ¨access denied¨ WHY ? I cannot tell...

Please send the diagram to:

arnaldo dot coro at gmail dot com (sent this way to avoid bots from using the address...

The voltage fed to the detector tube's plate should be at least 36 volts regulated (using three 12 volts zener diodes in series... For a bit more audio output add one more 12 volts zener diode to provide 48 volts... Screen grid regeneration control with a multi turns potentiometer provides silk smooth approach to the critical operating point required for CW and SSB reception. By the way, the receiver picks up digital modes like PSK31 with good stability. You can use a triode/tetrode or pentode audio tube like ECL82 for room filling volume with a loudspeaker

73 and DX

Just a tidbit note about EBAY URLs.

EVERY item on ebay can be accessed by their unique ITEM number which
appears next to
/itm/

so you can leave off everything after the "?" when sharing EBAY items.

Hi Hue Thanx for the Response. I a looking further into the Kit for my
Seniors SWL Scanner Clubs STEAMPUNK Radios project(s).
Antique Components and modern electronics for Objets d'art and a simple
but highly functional Radio,Crystal, Regenerative & TRF.

Hi Group
Three new topics
A) Has anyone tried to convert a Grid Dip Meter into a Radio?
B) Can any assist with a simple semiconductor circuit to use in converting
some Antique TRF Radios with 3 Tuned RF Stages?
I am thinking of Radio on a Chip for Detector and Audio.
C) Speaking of Radios on a Chip is there a way to make it an RF Amplifier
by not shunting off the RF to ground?

Actually, the last reference (link) above shows such a circuit with no tickler coil. The author used an old ARC-5 type of tapped coil, but equivalent dimensions are given in terms of form diameter, number of coil turns, and tap. I will be building that same circuit in the near future and will try to fine tune the design even more.

I found a similar circuit from the 1935 ARRL Handbook and built it, as is. I found it regenerated fine even with a plate voltage of 32 volts, D.C. I then built another version to fine tune the design even better. I replaced the 6D6 with a 6SK7, and the 76 with a 6J5. I used a discarded 32 volt D.C. power brick from an old printer, and a 6 volt D.C. power brick for the filaments. It worked out so well I am considering further refinements so I could use it as part of a homebrew QRP rig for 40m.

By the way, the ARRL used this same circuit in the 1936 Handbook. It can be Googled and downloaded from the Internet.

What did you use for the audio inductor? I am pretty certain you didn't find a 500H choke. (actually, I suspect, even without hard numbers, that a good portion of the old audio inductors are gone bad by now – the combination of very thin wire, like #38 to #40, and acidic elements in the
insulation or solder flux.)

This, my addendum to the online manual, may help a wee bit. But I'm not going to draw out a clarified schematic for you.

RF daughter board……... Detector daughter board
(schematic coil contact # / daughter board alpha named contact)

1 B…… antenna winding, bottom…….feedback winding bottom
2 A…….antenna winding, top……..feedback winding top
3 C (CX)……. varactor……varactor
4 D (CX)……..RF tube grid……detector tube grid
5 E…….tuning coil, top. (5E connects to 4D)……..tuning coil top
6 F…… ground; tuning coil bottom……..tuning coil bottom

For the MW broadcast band, you wire a jumper across the CX connection (3C to 4D). The inductors are axial lead miniature inductors
180 uH, all four windings. Kind of odd that the feedback winding is the same as the tuned circuit instead of the usual percentage of the
tuned coil, but maybe the lessened gain of the tube at these voltages doesn't make that quite so squirrely. The feedback and det inductors
are bent closer or farther apart to get the feedback in the right range. For the shortwave coils, CX connections have instead a 470 pF
installed, to decrease the tuning range to better accommodate the lack of any fine tuning control.
I would like to see what the 6-pin sub board connector looks like. I have no idea what style it is, is it an off the shelf IC connector?

Yes, this is the same circuit, as in the 1935 ARRL Handbook. Hue had a question about the 500 h audio choke. I just grabbed an old audio output transformer from the junk box and used it as the audio choke. It came from a five tube AC/DC broadcast radio, which used a 50L6 tube, as audio output. I used only the primary winding as the audio choke, leaving the secondary winding unconnected. It worked fine.
Also, I eliminated R4, a 25,000 ohm, 2 watt resistor. R4 is necessary at higher B+ plate voltages, but was eliminated here because I was using only 32 VDC for my plate voltage. Since I was powering the tube filaments with 6 VDC, I eliminated the resistor across the filaments, and powered the filaments directly.

OOPS, must proofread, I had exchanged A and B on the plugins.

RF daughter board……... Detector daughter board
(schematic coil contact # / daughter board alpha named contact)

1 A…… antenna winding, top…….……..feedback winding bottom
2 B…….antenna winding, bottom..……..feedback winding top
3 C (CX)……. varactor……varactor
4 D (CX)……..RF tube grid……detector tube grid
5 E…….tuning coil, top. (5E connects to 4D)……..tuning coil top
6 F…… ground; tuning coil bottom……..tuning coil bottom

For the MW broadcast band, you wire a jumper across the CX connection (3C to 4D). The inductors are axial lead miniature inductors
180 uH, all four windings. Kind of odd that the feedback winding is the same as the tuned circuit instead of the usual percentage of the
tuned coil, but maybe the lessened gain of the tube at these voltages doesn't make that quite so squirrely. The feedback and det inductors
are bent closer or farther apart to get the feedback in the right range. For the shortwave coils, CX connections have instead a 470 pF
installed, to decrease the tuning range to better accommodate the lack of any fine tuning control.

Pretty clever to use the plugin PC board for the tuning elements. I took a better look at the Ebay photos, which I really should have scrutinized
in the first place. There is enough info there you could build it from scratch. Looks like the DL96 tube is pretty similar to the 1L4 except the
DL96 has tapped filament for 3 or 1.5 volt option.

Topic: 28229 Message: 28253

Interesting that the lower inductance choke worked out so well. I am guessing, purely guessing, the output transformer is maybe 5-10 H. I was going to see what the inductance of the high voltage windings of some power transformers was, like old scope transformers with a thousand volt winding. I measured the inductance of some 400 Hz power transformer HV secondaries and they were in the range 30-40H. Made me look at 400 Hz power transformers in a new way.
I have one of this circuit breadboarded from way back then. I think maybe someone soldered it with the wrong kind of solder because all the contacts are corroded and need renewing.
-H

>Yes, this is the same circuit, as in the 1935 ARRL Handbook. Hue had a question about the 500 h audio choke. I just grabbed an old audio output transformer from the junk box and used it as the audio choke. It came from a five tube AC/DC broadcast radio, which used a 50L6 tube, as audio output. I used only the primary winding as the audio choke, leaving the secondary winding unconnected. It worked fine.
Also, I eliminated R4, a 25,000 ohm, 2 watt resistor. R4 is necessary at higher B+ plate voltages, but was eliminated here because I was using only 32 VDC for my plate voltage. Since I was powering the tube filaments with 6 VDC, I eliminated the resistor across the filaments, and powered the filaments directly.

Hue, you are probably correct on your estimation of the inductance of my junk box audio transformer, used here as an audio choke. I read many years ago that the higher the inductance of this choke, the higher would be the expected audio output in the headphones. One could also obtain higher audio volume by use of a pentode, instead of a triode, for audio output. On my recent breadboard experimental version of this receiver, I will incorporate that idea.

I'm now using a tuning capacitor from an old ARC-5 type transmitter (junked 50 years ago, from a unit with bullet holes in the enclosure case from WW2!) as the main tuning capacitor in my most recent breadboard build of this receiver. This capacitor is rugged, and has a nice vernier dial mechanism, built in. It almost make the bandspread variable capacitor, unnecessary. I'm using 14 gauge solid copper wire for all detector wiring, to improve stability of the circuit. The RF choke is also from the junk box, and physically appears to be the same size as a typical 2.5 mh, 50 ma choke.

I also placed a small variable capacitor in series with the antenna. (This was not shown in the original 1936 schematic diagram.) This capacitor helps somewhat to reduce coupling and signal strength thus minimizing overload on strong signals.

The adventure continues!

Some progress on the 30-volt regen… Audio stages are hooked up and working, see attached schematic. The total gain wide-open is 60 dB. I might need a volume Control…?
Both B+ and heater are fed from an old 30 V printer power supply.
Regards,
Mark

Yay, I can say it's actually a radio now! Last night hooked up the 9GH8 pentode as the regen stage, and I heard broadcasters on 49 meters, about as loud as I expect. I can hear them well enough to ID (RHC for example) but still needs some work; audio is distorted. It's at the prototype stage, built tumbleweed style on an old AA5 chassis, with whatever wire and parts happen to be within reach. So getting up and making another trip to the junk boxes may improve things ;-) I did use the Hartley oscillator . . . I like them since there's one less chance of a wiring error.

My goals for this project are to get headset volume from low voltage using tubes, and to not use anything I bought new. So I have the odd-ball TV tubes, cap from an old AM/FM tuner, coil wound on a pill bottle, and other parts from various junked devices. Now I'm looking at the big knurled lid from a peanut butter jar and trying to imagine how to make it into a nice tuning knob ;-)

Yes, Mark, you have the right idea. Build your radio with whatever parts you can find that work from your junk box. As long as it eventually works as well as you expect it to, and you are happy with it, who cares what it looks like.
My junk box has been growing for the last 50 plus years, and now takes up a large chunk of my basement. I've used my junk box a lot for parts to build similar devices. For example, in my version of the two tube regenerative radio from the 1935 ARRL handbook that I described here on this group, all parts came from my junk box.
My latest refinements in that circuit, after going from a 6D6 to a 6SK7, and a 76 to a 6J5 tube was to replace the 6J5 (single triode) with a 6SN7 (dual triode) for an extra stage of audio (after adding appropriate circuitry for the added triode section). This worked out so well I had to add a volume control so I don't blast my ears off when listening to strong signals with headphones. Not sure if this will adequately drive a speaker yet, but that is my next experiment (and an easy one, at that).
Junk boxes are great! I just found a ten turn potentiometer of about the right value called for in the original circuit. I'm going to see if I can get ultra fine regeneration control by use of this part.
The nice thing about building such a circuit, bread board style, is that one can easily make changes in the prototype version, before finalizing the design for the "end product."
... To be continued...

Hi all,

Last week I put my 10M beacon back on the air after having it off-line since January. I've already gotten feedback from Washington State (nearly nightly) and Arizona. Before taking it off air in January it was heard coast to coast, New Zealand, Australia and frequently into Hawaii.

Yeah, I do things 'bass-ackwards', have the beacon on when the sunspot cycle is poor and off when it's good. It's a Realistic HTX-100, pushing 25 Watts CW (20 Watts to antenna after 75' of coax loss). Antenna is a Cushcraft AR-10 Ringo about 14' above ground.

It's on 24/7 on 28.290MCs, keyed at about 11WPM.

To keep it on topic for this list, I'd be especially curious if anyone can hear it on their regen receiver???

28269. Do regen-based transceivers radiate RF even when receiving?

Yahoo group: regenrx (2016 — 2017)
Date: 2017-06-11 16:29:43 UTC
From: Ottavio Caruso
Topic: 28269 Message: 28269

Interesting topic on the GQRP mailing list, which I cannot link because it's not public, about the Pixie. (Yes I know, the Pixie is not a regen, but please read on!)

So, one the posters mentioned that he measured 800mw out at TX and 80mw out at RX.

As my theory skills are lacking, I asked why this happens and if it is normal, the answers I got were:

"Yes they do radiate on Rx. This is because the xtal oscillator is driving the PA transistor which is biased to a low current (about 1mA) & this is connected to the antenna via the low pass filter."

and:

"It is a characteristic of all direct conversion receivers and super-regenerative receivers because the local oscillator is in-band."

Now I assume the last poster meant regenerative instead of super regenerative, but in any case can anyone translate the statements above into plain English if possible?

Thanks.

if the local oscillator is not isolated from the antenna it can radiate. By PA transistor I assume you meant the transmit final amp. That should biased well off during receive. I don't know anything about this radio or it's topology other than what you have said.

I have two regens that I use. One is a National SW-3 and the other is an RCA RAK-7. both of them have good isolation and shielding. I absolutely cannot detect the oscillating detector in the RAK with two rf amps (for isolation - not for weak signal amplification) and more shielding than the SW-3. The SW-3 has one RF amp and adequate shielding but less than the RAK. I can't detect the oscillating detector outside the cabinet but I can if put the snooping radio's antenna wire just inside the box near the detector's 'silo'.

Somebody's plain, straight through regen with no thought to shielding radiates a bit. How far is not really known. Submarine radio op to captain "captain there is a signal from a regen radio due east". Captain "maybe it's that one right over there" pointing at the ship 100 yards away. <evil grin>

Hello Ottavio

While receiving, the PA transistor is acting as a switching mixer. The oscillator is still driving the basis of the PA, while the emitter is not pulled to ground. I measured amplitudes between 50mV and 150mV at the antenna connector. This depends a little bit on the frequency and which pa transistor is used. Once i managed, to neutralize this radiation, but couldn't repeate it with another circuit.

** that he measured 800mw out at TX and 80mw out at RX

Using my measurements for calculation, the rx radiation should more likely be in a range of 50-150µW. But still annoying, if you like to listen to your own signal, using your station receiver.

All three (super-regen, regen-receiver in autodyne mode and DC-receiver) are radiating inside of the pass band. With exception of the super-regen this can cause hum, while receiving your own radiated signal again. The hum disappeares, when u use them in the nature / back packing and run it from a battery.

Best regards,
Bernd

Yes... When the detector is adjusted to receive CW, it oscillates to provide a signal against which the incoming CW can heterodyne and make the audible sound of morse.. This signal also radiates as well as detecting.
With modern solid state, it still happens but the power is very low and not a serious problem. However the old valve / tube versions entailed QRP transmit levels of power which radiates via the antenna.
Today it would be a nuisance if heard just as a standing weak carrier but when these circuits were used in clandestine communications during WW2, it was a signal on which the enemy could carry out direction finding techniques, "Homing" often to the downfall of the operator who kept transmissions short for the same reason but left the Rx running steadily whilst monitoring a pre- agreed freq. and awaiting a pre-arranged time sked.

On AM this stage gives lots of RF gain but is just below the oscillating level and does not radiate.
The answer was a fully screened regen rx but with an RF amplifier (even low gain) which prevented
regen. RXs from radiating & thus revealing its location.

Regen. is an early version of Direct Conversion.
Modern DC receivers simply have a separate VFO to inject into the mixer and not the detector "regenerating" and mixing in itself.
Nonetheless the oscillator would need to be taken into design if radiation were to be avoided although the previously mentioned very low power would possibly make it insignificant unless the man next door were also
a ham operator, listening on the same QRG!

Yes, the base collector capacity of Q2 is coupling a small portion of the oscillator signal to the antenna.

I can only think of one 'spy radio' used in Europe that had the antenna go right to the regen detector stage – the famous "Paraset", but it was only used
in small numbers, and maybe only in Norway; a very small minority of the total variety and number of spy radios used in the European war. The rest were
either regens with an RF amplifier stage or some variety of superhet.

Even the LO of a superhet can leak through to the antenna a wee bit,
depending on the design and physical build. In a regen, the leak is
at such a low level that it only really affects the operator and,
perhaps, a neighbour who happens to be tuning around at the time.
In WW2 when detection of a regen in listening mode was a possible
issue, CW radiation during transmission was far more likely to be
radio-located.

Keep in mind the idea that detecting radiation from a regenerative receiver or the local oscillator of a superhet wouldbe significantly easier if there was a very quiet environment, such as in the middle of anocean. After all, if the receiver is several hundred miles from any othercompeting signals, background noise or QRM would be much less. In time of war, the likelihood of casual signals wouldbe low. Many operators maintained "radio silence" as a normal routine.

Hi,

During the war there were horrific losses. Any conceivable risk was mitigated if it could be. When use 20-20 hindsight the fear of being discovered by enemies DFing your regen was not warranted. It certainly seems like a reasonable concern. Nobody has produced any logs, action reports, etc that any enemy was ever detected by DFing their receiver. Their transmitters - certainly. At sea other vessels would be located from their machinery noises, their transmitters, or by line of sight contact well before any oscillating receiver detector would be heard. There are statements from captured former enemy officers that in fact, that never happened. If I was around in 1939 I would have worried about that too.

There is a possibility ashore that oscillating regens or even superhets that radiated minuscule signals could be DFed from a football field length away. Apparently super-regens are worse. The citations I had for that are vague and do not account for the operating conditions. Jamming a VHF repeater 500 feet in the air a mile away? C'mon. That's obvious.

Looks like "the enemy" truncated your schematic attachment :-)

Times have changed: now we must worry about inimical cyber-location.

Hi Ottavio,

Those guys all those years ago were concerned about *exactly* the same thing as you - rf pollution. But the stakes for them were very much higher than they are for you and I. We are not going to die for making a mess. Aren't we lucky! The whole point of that is there isn't much radiation and even that can be stifled. How to do that was included in the messages. Do you have more questions? Do you have missing citations?

A common base (or grounded grid) stage ahead of the detector won't give you much forward gain, but it will help out in the realm of antenna isolation. They have maybe 10db of forward gain but much higher loss in reverse. A 1 watt signal would become a 1 microwatt signal.

The last regen I built used two dual triodes with 24v on the plates. The RF amplifier was grounded grid and used three chokes in series, two 1mh and a 100uh choke, all green epoxy. The idea was to make the series load have a high reactance even as the frequency rose. Still, reception wasn't great above 4 MHz.

With a better scope and test equipment, I'd like to repeat the experience with 90v on the plates. I'd be able to calibrate the front end and see exactly where the deficiencies lie.

Hi Ed,

Depending on tube types and even individual tubes you can start getting good results with about 45 volts B+. I have tried reduced B+ on several tube radios and I switched to 90 volts on my six tube superhets. Heresy, I know - apologies. Those radios had noticeable reduction in performance at 45 volts but I did not make any accommodations in screen and grid bias circuits (more important in the screens) for the reduced B+. I feed mine from 9-volt batteries in series stacks. They run the radios for a satisfying long time. They should perform at least as well in a three or four tube regen. There are "battery" tubes that are intended to run very well on plate voltages as low as 22 volts (and will probably thrive on less). The filaments (not indirectly heated cathodes) also draw very low current for practical battery operation. The place where you will find trouble is in the audio output. If you want loudspeakers that rattle your windows be prepared to buy a lot more batteries! I use Hi-Z cans. I could also get away with using a set of speakers with solid state amplifiers in them as sold for computers and such. Is that cheating? I admit I have done that before. But I also have fed the output from a tube regen into a computer soundcard and then applied digital processing. Oy!? (quoting Tim "The Toolman" Allen)

Since ~10 years i have built and tested many different regenerative circuits. Most of them have been teared apart, to start the next project. I found, that the radiation can be very different. Some circuits, like the Armstrong are able to radiate a lot, if the regeneration is turned up too far. Sometimes i measured 1-2 Volts on the antenna connector. All tube regens, where the plate is driving the feedback coil, should be able, to do the same. One of my recent receivers is a hartley/eco circuit. It is hard, to see anything on the oscilloscope, so i only can guess the max. voltage is below 10mV.

Bernd

Hello Jordan,

you could try a 1L4 or the Russian 2SH27L (2Ж27Л) and connect them as a triode. Both can manage a cathode current of ~6mA. The 1L4 is a apprupt cut off type and should work well as a detector. Also the 2SH27L has already been used successfully in regenerative receivers. The should work well from ~30 Volts and above. Both are easily available and not expensive. Then calculate and connect a series resistor in order, to run the tube from the same filament voltage.

Most of the pencil tubes have a max. cathode current of ~1...3mA, but sometimes this is enough. Like the 5678, the 1AD4 or 1SH17B (1Ж17Б).
http://www.elektronikinfo.de/techpic/strom/1j17b.gif
http://www.elektronikinfo.de/techpic/strom/1j17b.gif
They can easily be hidden in the bottom / socket of an old, defective tube. Afterwards you should label it with "UX 226R" for example, to mark it is a replacement.

There is another russian tube, which could be useful, the 1P24B (1П24Б). As a transmitter, this little tube has a power output up to >2 watts. Never tried, if it works as a detector, but it should be a apprupt cut off.
http://www.radiovilag.hu/images/1P24B.pdf http://www.radiovilag.hu/images/1P24B.pdf

Best regards,
Bernd

Hi
Thanx to all for your timely responses.
As part of a STEAMPUNK Radio project using Antique/Vintage components and building from scratch we are exploring the retrofit of some complete Radios. To remove the Cabinetry and show the components. The need for lower voltage powering is one of safety as well as economics.
TRF Radios like Atwater Kent Model 20C
Regenerative Radios like the Radiola III & IIIA as well as Westinghouse RADA

Thanx

Apologies in advance . . . I recall seeing something about improvements or corrections to Morgan's schematic, but dang I can't find it now. Maybe someone better with Google can, or maybe the site was taken down.
What I recall is the writer saying that when wired as drawn the regeneration was touchy . . . a sudden transition from non-oscillating to oscillating. I *think* his fix involved a smaller value pot, maybe 5k, and adding a jumper to make the pot a rheostat.

I thought I'd printed this out and tucked it into my copy of "The First" but no dice. Sorry for being vague and not having a reference to link . . . I could be way off with my recollections, but if nothing else it's an avenue for experimentation once you get it going. Good Luck!

28306. Self-resonant frequency of chokes - measuring

Yahoo group: regenrx (2016 — 2017)
Date: 2017-06-19 09:25:08 UTC
From: les.au49@...
Topic: 28306 Message: 28306

I have a 1mH "formed" choke.

Actually I have a packet of these ... but for the purpose of this posting I'll consider a single choke.
My choke is modern. It's not one of those nice "pi-wound" chokes that James Millen invented.
My choke could easily be mistaken for a 1/2 watt resistor.

How do I measure the self-resonant frequency?
All methods of measurement welcome.

Les

28307. Re: Self-resonant frequency of chokes - measuring

Yahoo group: regenrx (2016 — 2017)
Date: 2017-06-19 10:19:05 UTC
From: les.au49@...
Topic: 28306 Message: 28307

Here is my method: I connect a 4700 resistor across the choke. (In parallel with the choke.)

I wind a 5 turn link around the body of the choke.
I feed the link with a 300mV signal from an RF generator.

I connect a SECOND link around the body of the choke and connect my CRO to the second link.

Starting at a low frequency I sweep UP in frequency.
Around 7MHz I see a few mV appear on the CRO. At first the signal is distorted, but increasing the frequency to 11MHz I see the signal appear as a sine-wave. There is a broad peak in the observed signal strength between 11 and 12 MHz.

But I don't believe the SRF of my choke is that high.
What do other list-readers think?

Les.

If you're talking about the green epoxy coated chokes, I think the mfr lists their SRF as somewhere around 790 KHz. I've often thought of making 455 KHZ IF filters using them.

One way to measure inductor resonant frequency is to make two small capacitors. For MF, you could make them 10pF. Use some sheet metal bent at a 90 degree angle to make one plate. Two plates, bolted to an insulating base facing each other, form a capacitor.

Place the two caps in series, insulated from a ground plane. One plate connects to a signal generator, another to a scope, and the junction in the middle to the choke you are measuring. Sweep across frequencies until you find a peak. The small capacitances isolate the choke from the wiring in the signal generator and scope probe.

Hello Ed:

My chokes are green, and they appear to be covered with epoxy - as far as I can judge.

This means my suspicion of my observation is reasonable, because I'm out by a factor of about x10.
(700kHz vs 7Mhz.)

Reading your description it seems I should make a "T" - with the two caps in series across the "T".
If I understand you correctly the choke forms the vertical bar on the "T" - yes??

I have handfuls of 2/4.7/10pF caps. Do I still need to form caps from angle metal?

Thanks for your info!

Les

Yes, form a tee. There are other ways to do what I suggest but this is one that makes the most sense to me.

If you have small value capacitors, no need to fabricate your own. The key is very light coupling to the resonant circuit. It will develop voltage as it reaches resonance.

Hi Ed,
Ha! I have a handful of 1pF capacitors in my parts drawer.
I'll use that value.
I always wondered what I might do with such a low value.
Now I know. It's 4:45 AM so I won't do anything at the moment, but tomorrow evening ....

I have several values of RF choke - 1mH, 1.5mH and so on. Some lower (eg 47uH)
The "standard" circuit for a regen set gives the value of the plate tickler choke as 2.5mH, but I suspect that value came from the days when regen sets tuned below the AM BC band. I suspect (without trying) that a 1mH choke will work well in the tickler circuit. (or even less if the set doesn't tune the BC band.)

Here, in Australia, the national public broadcaster is pushing digital radio. Maybe the AM BC band will "go" in 20 or 50 years?

Les

The tickler coil is a link that couples the plate back to the grid circuit. It's usually a handful of turns on the same coil form as the tuning coil.

I think what you are referring to is the plate choke, which connects B+ to the tube for it to operate. Those are normally a high value to confine all RF current to the plate.

Those normally have a low resonant frequency but can still perform at frequencies somewhat higher, because the small self capacitance is still a high impedance at frequencies above resonance.

The standard bank wound come you see in many projects supposedly has an SRF of about 1700 KHz but people are still using them to the upper end of HF.

Hello Ed,

Thank you for correcting my poor terminology "plate tickler coil". I obviously mean the RF choke in the plate circuit.

MEASURING THE SELF RESONANT FREQ.
I used the method you describe. Here are my observations:

Choke value Self Resonant Freq.
mH (a) (b)
1000uH 0.77MHz not recorded
1500uH 1.09MHz 1.26MHz

I used two methods of measurement. (a) as you described.
(b) An adaption of your method. I moved the CRO from the capacitor to a 4 turn link wound around the body of the choke. The resonance peak is easily seen, and at 1.26 measured 36mV (about 1/10 of the input signal).

The "Q" of the choke is about 3.5

Interesting adaptation. I'm surprised that a higher value choke has a higher resonant frequency.

As I said, I want to try the epoxy chokes as tuned filter transformers. If I can't get them to work well enough, I could try the larger toroids which have the same inductance with heavier wire. I'd have to couple the circuits with a small capacitance to make the filter effective.

I tried winding my own if transformers once. I don't know how well it worked because the entire radio wasn't doing so hot. I feel like, had I started simpler, I would have gotten better results.

Assuming the equipment isn't lying, I would suspect that capacitance within the choke is causing the higher frequency of resonance, or the markings are wrong.

Every year TARC (Turlock Amateur Radio Club) has been VERY active on field day, planning it months in advance, having an Ice Cream Social at the last club meeting before FD (usually about two weeks) to set up who will work which bands/modes, equipment, food and so forth. That Ice Cream Social was held last Tuesday and all went well. They usually hold FD on some private property where there is an Almond Orchard, banks of a river etc.

Well, today for safety reasons the TARC Officials decided to completely cancel FD this year and have put the notices out, announcing it on the repeater during the W6BXN/R repeater ID's, etc. . . It's ALWAYS hot here in the central valley at the end of June, but they were afraid that this heat wave that in in the middle of this year might cause some very severe medical problems, especially for the older members. I don't think it's EVER been cancelled before. This week the temps have been near record levels, right now (2:00PM) my outdoor remote thermometer says it's 108F outside, the "Weather Underground" web site says it's 108.7F here in town.

This really doesn't affect my FD plans, I'd already planned on running it from home in "Class 1E" (from home on emergency power). I've done that for years, can't handle the heat of operating in a tent outside, etc.

Hello Jim,

Rule #1. Trust you're instruments. Mostly they aren't lying.
Rule #2. Don't trust yourself. If you're like me you tell lies, and specifically in this case that's what I did.
The two values in the first column are reversed. I often make mistakes like that.

Les.

I measured the values in reverse order, (columns 2 & 3) Greatest inductance first.
Then I wrote my posting (and lost it).
When I re-typed the posting I wrote the value of the chokes in ascending order, but I didn't change the order of observations in the table of results. Lab-books show many errors like this (if you know where to look). I can assure you, more inductance gives a lower frequency for self resonance.

If anyone has a table showing ALL the self-resonant frequencies for these chokes, PLEASE TELL ME WHERE I CAN GET A COPY.

Wow, Phil!

Here, overlooking the Atlantic it was a cool 34°C today.
But still dodgy for the wonky-hearted, so I guess the
field day deferral was warranted! I like the idea of
an Ice Cream Social. (Maybe we'll return to °F post-Brexit :-)

I am scheduled for an extra bit of stainless steel this
week, so I hope my slot does not get sequestered by
a more urgent heat-triggered case!

Keep cool and enjoy your exclusive FD!

Michael 2E0IHW

The article seems to be pretty well hidden, altho I'm sure it was discussed here in the past. I didn't see it in the group files, nor did any combination I tried to Google have success.
If no one comes up with it, you might have to go to americanradiohistory.com, select Short Wave Craft, and maybe start with 1934 and just start looking at copies.
Then if not 1934, move one year up and down. Good luck! (I decided I could not keep all the hundreds of lbs. of magazines I had, and disposed of them. I sent many to that radio history site.)

Thank you all for the info and comments. Hue, I'll look thru SWC as you suggest.

From the Nothing New Under the Sun Dept., here is another somewhat like RX.

73, Lou VE3AWA

This page did not get thru on the first go...

28331. Autodyne Receiver

Yahoo group: regenrx (2016 — 2017)
Date: 2017-07-03 03:07:03 UTC
From: w9ac@...
Topic: 28331 Message: 28331

I recently picked up a nice regen receiver on eBay that's based on Grammer's ca. 1933 autodyne circuit. I did not expect it to be a functioning receiver. My intent was to cannibalize it for parts -- until I plugged it in and tried it. The receiver is mostly adapted from Grammer's 1933 article. However, a few differences:

- Tube lineup is 77-77-78. Similar to the 58-57 series type but with 6V filaments;
- Interesting use of the 78 as the audio output tube rather than a 76 triode;
- No B+ wrapped around the skull; a UTC transformer is inserted in the 78 plate lead with a 600-ohm secondary;
- RF/Detector tuning is ganged just like Grammer's autodyne and the National SW-3;
- National SLF 270 deg. cap used as in the SW-3. National Type B Velvet Vernier dial;
- A shield plate is inserted between the RF and detector cap sections. A James Millen "no-no," but not sure why it didn't work for him. Isolation seems excellent but perhaps not on the upper bands;
- Detector coil band-spreaded much like the SW-3. 40m range is 7000 kHz to 7250 kHz across 270 degs;
- External supply uses an OD3 VR. No tuning changes with line voltage.

The RF gain circuit replicates Grammer's autodyne and uses the same component values. No hum, no howl, no buzz, and no perceptible drift on 40m after 5 min warm up. The regen control is very smooth.

The receiver appears to have been built in the 1950s. The builder used many period-correct components, but not all. Component placement is well-thought. Many components come to a single-point-ground and underside wiring is tightly laced.

Overall performance is at least as good as my National SW-3. Of course, having the B+ and screens regulated really helps with small changes in line voltage. Still amazing how well these receivers worked when construction practice matches a good schematic design.

For those curious, see eBay item number is 352053894601.

Manhattan style uses an unetched pc board as the base. then small pc board pads are glued down, using super glue. these are isolated from the lower ground, and parts are mounted here. except anything attached to ground go direct to the lower board. the original poster gave a picture, and many references are on the web.

Curt

As pictured - it received 7.0 to 12.0 MHz. I did pick up some 40 meter CW signals, but the short wave broadcast stations on the 31 meter band were loud. I want to re-arrange the tuning so it tunes the 40 meter ham band only. That would mean placing a variable trimmer cap across the cap and a lower value cap in series. The main tuning cap is perhaps 20-100 pF. If I put a 100 pF cap in parallel and a 20 pF cap in series, then it would tune 100-110 pF which is what I think is needed.

What frequencies does it hear?
